1 Introduction

Group representation theory is a field of mathematics that applies linear algebra to study properties of groups. The field itself originated through a letter from Dedekind to Frobenius in which he noted that, given $f = \det A$, where A is the Cayley table of a group of n elements, by factorising f into irreducible polynomials, $f = \prod_i f_i^{d_i}$, we have $d_i = \deg f_i$. And this led Frobenius to invent group representation theory.

Group representation theory is applicable in many different areas.

- Group theory arises in Klein's "Erlangen program" as symmetries of geometric spaces.
- Burnside in 1904 proves the following using representation theory (and so shall we later on)

Proposition 1.1. Let G be a group such that $|G| = p^r q^s$ where p, q are prime and $r + s \geq 2$, then G is not simple.

- In number theory, representations of Galois groups arises in the number field case

$$\overline{F}/F, \mathbb{Q} \subseteq F, [F : \mathbb{Q}] < \infty,$$

which has implications in Wiles' proof of Fermat's last theorem.

- In chemistry the symmetry and rotation of molecules can be represented by group actions.
- In quantum mechanics, spherical symmetry gives rise to discrete energy levels, orbitals, etc.
- In differential geometry, the vector space of solutions is a representation of the symmetry group of an equation.

Recalling the definition of a group, informally, the representation of a group G is a way of writing group elements as linear transformations of a vector space such that the natural group properties are satisfied.

Some examples of group representations are the following:

- For all group G , the trivial representation of G is ρ such that $\rho(g) = \text{id}$ for all $g \in G$.
- Let $\zeta \in \mathbb{C}$ be a n -th root of 1 and let $G = C_n = \{1, g, \dots, g^{n-1}\}$. Then $\rho : g^i \mapsto (\zeta^i)$ is a representation of G .
- In the case $G = S_n$, the mapping of $\sigma \in S_n$ to its corresponding permutation matrix P_σ is a representation of G .
- Another representation of S_n is $\sigma \in S_n \mapsto (\text{sign}(\sigma))^1$.
- Let $G = D_n$ the dihedral group of order $2n$. Then, a representation D_n maps elements of D_n to the corresponding 2×2 matrices which rotates/reflects \mathbb{R}^2 by the appropriate amount.

We shall in this module study and construct representations, and furthermore, classify up to isomorphism finite-dimensional complex representations of every finite group G .

¹ $\text{sign}(\sigma) = \det P_\sigma$

2 Fundamentals of Group Representation

Definition 2.1 (Representation). Let G be a group, then a representation of G is the pair (V, ρ) where V is a (finite-dimensional) vector space and $\rho : G \mapsto GL(V)$ is a group homomorphism.

Alternatively, we may consider a group representation of G is a group action $(\cdot) : G \times V \rightarrow V : (g, v) \mapsto v$ such that (\cdot) is linear with respect to the second parameter. In particular, we recall a group action (\cdot) satisfies $e \cdot v = v$ and $g \cdot (h \cdot v) = gh \cdot v$.

Definition 2.2 (Dimension of a Representation). If (V, ρ) is a representation of G , then the dimension of (V, ρ) is $\dim(V, \rho) = \dim V$.

Similar to other objects in mathematics, we introduce a notion of morphisms between representations.

Definition 2.3 (Homomorphism of Representation). Let G be a group and (V, ρ_V) and (W, ρ_W) be two representations of G . Then a homomorphism of representations is a linear map $T : V \rightarrow W$ such that for all $g \in G$,

$$T \circ \rho_V(g) = \rho_W(g) \circ T.$$

Furthermore, we say T is an isomorphism is bijective (or equivalently, it has an inverse which is also a homomorphism).

In particular, one might imagine the homomorphism as a linear map such that the following diagram commute.

$$\begin{array}{ccc} V & \xrightarrow{T} & W \\ \rho_V(g) \downarrow & & \downarrow \rho_W(g) \\ V & \xrightarrow{T} & W \end{array}$$

As with any definitions which work with finite-dimensional vector spaces, there are equivalent but “worse” (as we will have to choose a basis) corresponding definitions in terms of matrices. Nonetheless, these definitions with matrices are easier computationally and we shall recall the contrast here.

Clearly, if G is a group and (\mathbb{C}^n, ρ) is a representation, we have $\rho(e) = I_n$. Furthermore, we have a natural isomorphism between $GL_n(\mathbb{C}) \cong GL(\mathbb{C}^n)$ and more generally $\text{Mat}_{n,m}(\mathbb{C}) \cong \text{Hom}(\mathbb{C}^n, \mathbb{C}^m)$. Similarly, given a representation (V, ρ) , with $\dim V < \infty$, we may choose a basis B of V and write the representation as a matrix which we denote $\rho^B(g) = [\rho(g)]_B$. Thus, we may use first year linear algebra methods to manipulate representations.

Definition 2.4. Given two matrix representations $\rho, \rho' : G \mapsto GL_n(\mathbb{C})$, we say ρ and ρ' are equivalent/isomorphic if there exists $P \in GL_n(\mathbb{C})$ such that for all $g \in G$, $\rho'(g) = P^{-1}\rho(g)P$.

This definition is motivated by the following.

Proposition 2.1. Given (V, ρ_V) and (W, ρ_W) representations of G , we have $\rho_V \cong \rho_W$ if and only if there exists some $P \in GL_n(\mathbb{C})$ such that for all $g \in G$, $\rho_W^C(g) = P^{-1}\rho_V^B(g)P$ for some basis B, C of V and W respectively.

Proof. Exercise. □

Proposition 2.2. Given a cyclic group $C_n = \langle g \rangle$ with representations (V, ρ_V) and (W, ρ_W) of equal dimensions, we have $\rho_V \cong \rho_W$ if and only if $\rho_V^B(g)$ is conjugate to $\rho_W^C(g)$ for some basis B, C of V and W respectively.

Proof. Exercise. □

In fact the proposition above holds for the infinite cyclic group $C_\infty \cong \mathbb{Z}$.

2.1 Regular Representation

Let us first recall some definition about group actions though we will omit stabilizers, the orbit-stabilizer theorem and transitive actions (though it might be helpful to recall them from last year).

Definition 2.5 (Group Action). Let G be a group and X a set, then a group action (\cdot) of G on X is a function $G \times X \rightarrow X$ such that for all $g, h \in G, x \in X$, we have

- $g \cdot (h \cdot x) = gh \cdot x$,
- $1 \cdot x = x$.

Equivalently, a group action can be represented by a group homomorphism between G to S_n if $|X| = n < \infty$. We note that there exists a bijection between $\text{Perm}(X)$ (a.k.a $\text{Aut}(X)$ though we will avoid this term in case X has additional structures) and S_n with depends on a choice of $X \simeq \{1, \dots, |X|\}$.

Definition 2.6 (Kernel). A kernel of a representation (or group action) is simply the kernel of the corresponding group homomorphism, i.e. if ρ is a representation (or group action),

$$\ker \rho := \{g \in G \mid \rho(g) = \text{id}\}.$$

We say a representation (or group action) is faithful if $\ker \rho = \{e\}$, i.e. ρ is injective.

Definition 2.7 (Morphism of Group Actions). A morphism $T : X \rightarrow Y$ of group actions on X and Y is a map such that $T(g \cdot x) = g \cdot T(x)$ for all $g \in G, x \in X$.

This is also called a “ G -equivariant map” from X to Y and one can see the resemblance of this definition and the definition for homomorphisms between representations.

For any group G , it acts on itself in three different ways. In particular, we have the left regular action $g \cdot h = gh$, the right regular action $g \cdot h = hg^{-1}$ (where the inverse is required for associativity) and the adjoint action $g \cdot h = ghg^{-1}$. One can see that the left and right regular actions are isomorphic via $T(g) = g^{-1}$. On the other hand, they are not isomorphic to the adjoint action (consider $\rho_{\text{ad}}(g)(e) = e$ for all $g \in G$).

Proposition 2.3. Given two actions (or representations) ρ, ρ' on G , $g \mapsto \rho(g)\rho'(g)$ is an action (or representation) if and only if $\rho(g)\rho'(g) = \rho'(g)\rho(g)$, that is ρ and ρ' are commuting actions.

Definition 2.8. A subset $Y \subseteq X$ is said to be stable under an action (\cdot) of G on X if $g \cdot y \in Y$ for all $y \in Y, g \in G$.

In the case that $Y \subseteq X$ is stable, then we may restrict the action on Y to obtain a new action of G on Y .

Definition 2.9 (Orbit). Let $x \in X$, then $G \cdot x := \{g \cdot x \mid g \in G\}$ is called an orbit of x and we denote this by $\text{orb}(x)$.

It is not difficult to see that orbits are stable and in fact, as an exercise, one might show that $Y \subseteq X$ is stable if and only if it is a union of orbits.

In a group G under the adjoint action, we see that the orbits are the conjugacy classes². Thus, for every conjugacy class, we obtain an action on that class from the adjoint action on the whole group.

Example 2.1. Let $G = S_4$ and let $c = \{(12)(34), (13)(24), (14)(23)\}$. Then as c is a conjugacy class, we have the adjoint action on c

$$\phi : S_4 \rightarrow \text{Perm}(c) \cong S_3.$$

It is not difficult to show that ϕ is surjective and $\ker \phi = c \cup \{e\} \cong K_4 \cong C_2 \times C_2$. Thus, by the first isomorphism theorem we have

$$S_3 \cong S_4 / K_4.$$

Definition 2.10. Given a finite set X , let

$$\mathbb{C}[X] := \left\{ \sum_{x \in X} a_x x \mid a_x \in \mathbb{C} \right\},$$

equipped with the addition $\sum_{x \in X} a_x x + \sum_{x \in X} b_x x = \sum_{x \in X} (a_x + b_x) x$ and scalar multiplication $c \cdot \sum_{x \in X} a_x x = \sum_{x \in X} (ca_x) x$. This sum here does not represent some addition operation on X but a notational trick. One might instead consider elements of $\mathbb{C}[X]$ as functions $a : X \rightarrow \mathbb{C}$ equipped with point-wise addition and scalar multiplication.

We observe that $\mathbb{C}[X] \cong \mathbb{C}^{|X|}$ depending on a choice of $X \cong \{1, \dots, |X|\}$. Furthermore, we have $X \subseteq \mathbb{C}[X]$ and is a basis (if we interpret $\mathbb{C}[X]$ as a space of functions, the canonical basis is $\{a_x : y \mapsto \chi_{\{x\}} \mid x \in X\}$). In the case that X is infinite we can still define $\mathbb{C}[X]$ allowing only finite sums.

Proposition 2.4. If (\cdot) is a group action of G on X , then, the map $(g, \sum a_x x) \mapsto \sum a_x (g \cdot x)$ is a group action of G on $\mathbb{C}[X]$.

Definition 2.11. The left regular, right regular, adjoint representations are representations

$$\tilde{\rho}_L, \tilde{\rho}_R, \tilde{\rho}_{\text{ad}} : G \rightarrow GL(\mathbb{C}[G])$$

obtained from the left regular, right regular and adjoint actions

$$\rho_L, \rho_R, \rho_{\text{ad}} : G \rightarrow \text{Perm}(G).$$

Proposition 2.5. If X is any set with a G -actin, then for all $g \in G$, $[\rho_{\mathbb{C}[X]}(g)]_B$ is always a permutation matrix.

Proof. Exercise. □

²What are the orbits of the left action?

Definition 2.12. Given $(V, \rho_V), (W, \rho_W)$ representations of G , we denote

$$\text{Hom}_G(V, W) := \{T : V \rightarrow W \mid G\text{-linear}\}.$$

Proposition 2.6. Let (V, ρ_V) be a representation of G and $v \in V$. Then, there exists a unique homomorphism of representations $\mathbb{C}[G] \rightarrow V$ where $\mathbb{C}[G]$ is equipped with the left regular representation such that $e_G \mapsto v$ and thus,

$$\text{Hom}_G(\mathbb{C}[G], V) \cong (V, \rho_V).$$

Proof. For all $g \in G$, $c = \sum_{h \in G} a_h h$, we have

$$\begin{aligned} T(g \cdot c) = \rho_V(g)(Tc) &\iff T\left(\sum a_h gh\right) = \rho_V(g)\left(T\left(\sum a_h h\right)\right) \\ &\iff \sum a_h T(gh) = \sum a_h \rho_V(g)(Th) \\ &\iff T(gh) = \rho_V(g)(Th), \quad \forall h \in G, \end{aligned}$$

where the second if and only if follows as both T and ρ_V are linear. Then choosing $h = e_G$, we have $T(g) = \rho_V(g)(v)$ and thus T is uniquely determined on G and hence is unique as G is a basis of $\mathbb{C}[G]$.

It remains to show that the map T defined by $g \mapsto \rho_V(g)(v)$ is a homomorphism of representations. This is clear since

$$\begin{aligned} T(g \cdot c) &= T\left(\sum a_h gh\right) = \sum a_h T(gh) \\ &= \sum a_h \rho_V(gh)(v) = \sum a_h \rho_V(g)(\rho_V(h)(v)) \\ &= \sum a_h \rho_V(g)(Th) = \rho_V(g)\left(T\left(\sum a_h h\right)\right), \end{aligned}$$

where the fourth equality follows by the associativity of group actions. \square

2.2 Subrepresentation and Quotient Representation

Definition 2.13 (Subrepresentation). A subrepresentation of a representation (V, ρ_V) is a subspace $W \leq V$ such that $\rho_V(g)(W) \subseteq W$ for all $g \in G$.

Clearly, both $\{0\}$ and V are subrepresentations of (V, ρ_V) , and we say a representation is irreducible if these two subrepresentations are the only subrepresentations. We say a representation is reducible if it is not irreducible. In general, every 1-dimension representation is irreducible.

Proposition 2.7. Irreducibility is invariant under isomorphisms.

Proof. Exercise. \square

Proposition 2.8. Let G be finite and (V, ρ_V) is an irreducible representation of G . Then $\dim V < \infty$.

Proof. Let $w \in V \setminus \{0\}$ and let $W := \text{span}(\{\rho_V(g)(w) \mid g \in G\})$ which is a finite dimensional subrepresentation as G is finite and for all $h \in G$, $\rho_V(h)(\rho_V(g)(w)) = \rho_V(hg)(w)$. Thus, if $\dim V$ is not finite, we have found a proper subrepresentation which contradicts the irreducibility of (V, ρ_V) . \square

Definition 2.14 (Quotient Representation). For $W \leq V$ a subrepresentation, the quotient representation is $(V/W, \rho_{V/W})$ given by

$$\rho_{V/W}(g)(v + W) := \rho_V(g)(v) + W.$$

This is well-defined as W is stable under ρ_V .

Proposition 2.9. For $T : (V, \rho_V) \rightarrow (W, \rho_W)$ a G -linear map, $\ker T$ and $\text{Im} T$ are subrepresentations.

Proof. Let $v \in \ker T$, then $T(\rho_V(g)(v)) = \rho_W(g)(Tv) = \rho_W(g)(0) = 0$ implying $\rho_V(g)(v) \in \ker T$ and thus, $\ker T$ is a subrepresentation. On the other hand, for all $w \in \text{Im} T$, there exists some $v \in V$ such that $Tv = w$. Then $\rho_W(g)(w) = \rho_W(g)(Tv) = T\rho_V(g)(v)$ implying $\rho_W(g)(w) \in \text{Im} T$ showing $\text{Im} T$ is also a subrepresentation. \square

Proposition 2.10. For $T : (V, \rho_V) \rightarrow (W, \rho_W)$ a G -linear map, we have

$$\text{Im} T \cong V / \ker T.$$

Proof. Follows from the first isomorphism for vector spaces and it remains to check $V / \ker T \rightarrow \text{Im} T$ is G -linear. \square

Proposition 2.11. If $T \in \text{End}_G V$ is a G -linear projection (i.e. $T^2 = T$), then V is a direct sum of subrepresentations $\ker T \oplus \text{Im} T$.

Proof. Follows from the vector space case. \square

2.3 Maschke's Theorem and Schur's Lemma

Recalling internal and external direct sums of vector spaces, we will in this section introduce and prove a powerful result in representation theory known as the Maschke's theorem.

Definition 2.15 (Decomposable). The representation (V, ρ_V) is decomposable if there exists a decomposition $V = U \oplus W$ where U, W are non-zero subrepresentations.

Definition 2.16 (Semisimple). The representation (V, ρ_V) is semisimple if there exists a irreducible subrepresentations W_1, \dots, W_n such that

$$V = \bigoplus_{i=1}^n W_i.$$

Theorem 1 (Maschke's Theorem). If G is finite, then for all $W \leq V$ subrepresentations of (V, ρ_V) , there exists a complementary subrepresentation U , $V = W \oplus U$.

A direct consequence of Maschke's theorem is that every finite-dimensional representation of G is semisimple.

Maschke's theorem does not hold in the case that G is not finite. Consider $G = \mathbb{Z}$ and let

$$\rho : g \rightarrow GL_2(\mathbb{C}) : m \mapsto \begin{bmatrix} 1 & m \\ 0 & 1 \end{bmatrix}.$$

Then the only non-zero proper subrepresentation is $\text{span}\{e_1\}$ since e_1 is the only eigenvector and as ρ is a 2-dimensional representation, the only non-zero proper subrepresentation is 1-dimensional, hence an eigenspace. Thus, ρ is indecomposable but not irreducible, and hence not semisimple.

Proof of Maschke's Theorem. To prove the theorem, we will attempt to find some G -linear map $T : V \rightarrow V$ that is a projection, i.e. $T^2 = T$, such that $\text{im}T = W$ and so $V = \ker T \oplus \text{Im}T = \ker T \oplus W$.

In the case of linear maps, a map satisfying the above proposition must map

$$T(u + w) = Tu + Tw = 0 + w = w,$$

where $u \in \ker T$ and $w \in W$. As, $\ker T \oplus W = V$, this property uniquely identifies T on V . However, this map is not G -linear and so we will modify T such that it is G -linear.

By recalling that a linear map is G -linear if and only if it is conjugate with it self by $\rho(g)$ for all $g \in G$, let us define

$$\tilde{T} := \frac{1}{|G|} \sum_{g \in G} \rho_V(g) \circ T \circ \rho_V(g)^{-1},$$

such that it is in some sense the average of all conjugates over all g .

We will now show that \tilde{T} is a G -linear projection and $\text{im}\tilde{T} = W$. Indeed, for all $h \in G$, we have

$$\rho_V(h) \circ \frac{1}{|G|} \left(\sum_{g \in G} \rho_V(g) \circ T \circ \rho_V(g)^{-1} \right) \circ \rho_V(h)^{-1} = \frac{1}{|G|} \sum_{g \in G} \rho_V(hg) \circ T \circ \rho_V(hg)^{-1} = \tilde{T},$$

as $g \mapsto h \cdot g$ is bijective as it has the inverse $g \mapsto h^{-1}g$. On the other hand, it is clear that $\tilde{T}(V) \subseteq W$ as for all $v \in V$, $T(\rho_V(g)^{-1}v) \in W$, and as W is a subrepresentation, we have $\rho_V(g)T(\rho_V(g)^{-1}v) \in W$. Thus, as $\tilde{T}|_W = \text{id}|_W$, since

$$\tilde{T}w = \frac{1}{|G|} \sum_{g \in G} \rho_V(g)T(\rho_V(g)^{-1}w) = \frac{1}{|G|} \sum_{g \in G} \rho_V(g)\rho_V(g)^{-1}w = \frac{1}{|G|} \sum_{g \in G} w = w,$$

we have $\text{Im}\tilde{T} = W$ and \tilde{T} is a projection. \square

We note that we used the property of \mathbb{C} precisely when we needed $|G|^{-1}$ and thus, the same proof works for all field in which $|G|$ is invertible, i.e. of characteristic not a factor of $|G|$.

This decomposition needs not be unique. Indeed, if V, ρ_V is a trivial representation with dimension > 1 . Then any vector space decomposition is a decomposition of representations. For example, if $V = \mathbb{C}^2$, then

$$\mathbb{C}^2 = \{(a, 0)\} \oplus \{(0, b)\} = \{(a, a)\} \oplus \{(b, -b)\},$$

and in fact any pair of subspaces spanned by two linearly independent basis form a decomposition.

Proposition 2.12. For $G = C_m = \langle g \rangle$, (V, ρ_V) a representation of G , there exists a unique decomposition of (V, ρ_V) into 1-dimensional subrepresentations if and only if $\rho_V(g)$ has distinct eigenvalues.

Proof. Exercise. □

Lemma 2.1 (Schur's Lemma). Let V and W be irreducible representations of G , then

- every G -linear map $T : V \rightarrow W$ is invertible or zero;
- let $V = W$ be finite-dimensional, then every G -linear map $T : V \rightarrow V$ is a multiple of the identity, i.e. $\text{End}_G V = \mathbb{C} \cdot \text{id}$.

We note that the first property does not require V, W to be finite dimensional, and in fact it is true for arbitrary fields. On the other hand the second property only works for algebraically closed fields.

Proof. The first property is rather trivial. Indeed, if $T \neq 0$ then $\ker T$ must be $\{0\}$ as $\ker T$ is a subrepresentation and V is irreducible. Similarly, for the same reason $\text{Im} T = W$ and thus, T is bijective.

For the second property, we recall that the eigenvalues of T are the roots of the characteristic polynomial of T . Now since \mathbb{C} is algebraically closed, there exists some $\lambda \in \mathbb{C}$ such that $\ker(\lambda I - T) \neq \{0\}$. Now since $\ker(\lambda I - T)$ is a subrepresentation of V , as V is irreducible, we have $\ker(\lambda I - T) = V$. Thus, for all $v \in V$,

$$\lambda v - Tv = 0 \implies Tv = \lambda v \implies T = \lambda \cdot \text{id}$$

as required. □

Theorem 2. Up to isomorphism (and reordering), the representation decomposition is unique. That is, if $T : V := V_1 \oplus \cdots \oplus V_m \cong W := W_1 \oplus \cdots \oplus W_n$, then $V_i \cong W_i$ up to ordering.

Proof. We have $T : V \rightarrow W$ is a G -isomorphism map and so $T(V_i)$ is a subrepresentation of W . Then, as $W = W_1 \oplus \cdots \oplus W_n$, there exists some j such that $W_j \cap T(V_i) \neq \emptyset$. Thus, we have $T|_{V_i} : V_i \rightarrow W_j$ is a G -linear map between two irreducible representations. As $T|_{V_i} \neq 0$, by Schur's lemma, it follows $T(V_i) = W_j$. Now, since for $i \neq k$, $T(V_i) \neq T(V_k)$ as T is bijective and $V_i \cap V_k = \emptyset$, by pairing the V_i and W_j , we are able to correspond each V_i with a W_j . Reversing this process with T^{-1} , we are able to pair each W_j with a V_i and thus, we have $V_i \cong W_i$ up to ordering as required. □

Theorem 3. In the case that V is finite dimensional, there is a unique decomposition $V = \bigoplus_{i=1}^n V_m$ (up to reordering) if and only if in some decomposition, V_i are all non-isomorphic.

Proof. Suppose first that $V_1 \oplus \cdots \oplus V_n = V$, and V_1, \dots, V_n are all non-isomorphic. Then, for all G -linear maps $T : V_i \rightarrow V$, we have by a similar argument as above, if $T \neq 0$, there exists some j such that $T : V_i \cong V_j$. But as V_i, V_j are non-isomorphic for $i \neq j$, we have $T \in \text{End}_G V_i$. Thus, by the second part of Schur's lemma, there exists some λ such

that $T = \lambda \cdot \text{id} \mid_{V_i}$. Now, if $V = W_1 \oplus \dots \oplus W_m$, by the above theorem, WLOG, we have $T_i : V_i \cong W_i \subseteq V$. But we just shown $T_i = \lambda \cdot \text{id} \mid_{V_i}$ and so, $V_i = W_i$ and the decomposition is unique.

Conversely, consider that for any representation V_i , there exists infinitely many subrepresentations of $V_i \oplus V_i$ by taking

$$V_a := \{(v, av) \mid v \in V\}.$$

Thus, if $V_i \cong V_j$, we have

$$V_a \leq V_i \oplus_{\text{ext}} V_i \cong V_i \oplus_{\text{ext}} V_j \cong V_i \oplus_{\text{int}} V_j.$$

Denoting the isomorphism from $V_i \oplus_{\text{ext}} V_i$ to $V_i \oplus_{\text{int}} V_j$ as T , we have $T(V_a) \leq V_i \oplus_{\text{int}} V_j$ and by Maschke's theorem, there exists some subrepresentation U such that, U is complement to $T(V_a)$ and

$$T(V_a) \oplus_{\text{int}} U = V_i \oplus_{\text{int}} V_j.$$

Thus, as T is an isomorphism, $a \neq b$ implies $T(V_a) \neq T(V_b)$, we have found infinitely many non-equal decompositions of $V_i \oplus_{\text{int}} V_j$ and hence, also V . \square

Corollary 3.1. For V_1, \dots, V_n irreducible, non-isomorphic, subrepresentations of V such that $V = V_1 \oplus \dots \oplus V_n$ all subrepresentations of V are of the form $V_{i_1} \oplus \dots \oplus V_{i_m}$. In particular V has 2^n different subrepresentations.

2.3.1 Representation of Abelian Groups

Definition 2.17 (Centre). The centre of a group G is the subgroup with the underlying set

$$Z(G) := \{z \in G \mid zg = gz, \forall g \in G\}.$$

Proposition 2.13. Let (V, ρ_V) be a finite dimensional irreducible representation and let $z \in Z(G)$. Then $\rho_V(z)$ is a scalar, i.e. $\rho_V(z) = \lambda \cdot \text{id}_V$ for some $\lambda \in \mathbb{C}$.

Proof. For all $g \in G$, we have $\rho_V(z)\rho_V(g) = \rho_V(zg) = \rho_V(gz) = \rho_V(g)\rho_V(z)$. So $\rho_V(z) : V \rightarrow V$ is G -linear. Thus, by the second property of Schur's lemma, there exists some λ such that $\lambda \cdot \text{id}_V$. \square

Corollary 3.2. If G is abelian and if (V, ρ_V) is an irreducible representation of G , then $\dim V = 1$.

Proof. As for abelian groups G , $Z(G) = G$, we have $\rho_V(g) = \lambda_g \cdot \text{id}_V$ for all $g \in G$. Then, for all subspaces W of V , W is a subrepresentation. However, as V is irreducible, W must either be zero or V , and thus, $\dim V = 1$. \square

Corollary 3.3. If G is finite and abelian, then every finite dimensional representation is a direct sum of 1-dimensional subrepresentations.

The finite dimensional condition is necessary. Indeed, if F be a field $C \subsetneq F$ (then $\dim F = \infty$), e.g.

$$F := \left\{ \frac{P(X)}{Q(X)} \mid P, Q \in \mathbb{C}[X], Q \neq 0 \right\},$$

then F is an irreducible ∞ -dimensional representation over \mathbb{C} of $G = F^\times$ although the latter is abelian.

Corollary 3.4. The irreducible representations of C_m are up to isomorphism (\mathbb{C}, ρ_ζ) where ζ is a m -th root of unity. Furthermore, the irreducible representations of $C_{m_1} \times \cdots \times C_{m_l}$ are up to isomorphism,

$$\rho_{\zeta_1, \dots, \zeta_l}(g_1^{j_1}, \dots, g_l^{j_l}) = (\zeta_1^{j_1}, \dots, \zeta_l^{j_l}).$$

The above corollary is important as every finite abelian group is an internal direct product of cyclic groups, we have classified all irreducible representations of finite abelian groups. So, if G is finite abelian, then it has $|G|$ number of 1-dimensional representations.

Proposition 2.14. Every 1-dimensional representation of a group G is of the form (V, ρ_V) , $\rho_V(g) = \lambda_g \text{id}_V$ for some $\lambda_g \in \mathbb{C}$. Furthermore, two such representations are isomorphic if and only if the λ_g are the same.

Proof. The first statement is clear while the second state follows since, if $(V, \rho_V : g \mapsto \lambda_g \text{id}_V)$, $(W, \rho_W : g \mapsto \lambda'_g \text{id}_W)$ are two isomorphic 1-dimensional representations of G along $T : V \rightarrow W$, then given some $v \in V \setminus \{0\}$, we have $T(v) \neq 0$ and

$$\lambda_g T(v) = T(\lambda_g v) = T(\rho_V(g)(v)) = \rho_W(g)(T(v)) = \lambda'_g T(v).$$

Thus, $\lambda_g = \lambda'_g$. □

As all 1-dimensional vector spaces over \mathbb{C} are isomorphic to $GL_1(\mathbb{C}) \cong \mathbb{C}^\times$, we can simply only consider \mathbb{C}^\times as the vector space of all 1-dimensional representations.

Consider the 1-dimensional representations on S_n . Let $(\mathbb{C}^\times, \rho)$ be a representation of S_n , then by considering $\sigma(a_1, \dots, a_n)\sigma^{-1} = (\sigma(a_1), \dots, \sigma(a_n))$, we have

$$(ij) = ((1i)(2j))(12)((2j)(1i)),$$

and so (ij) is conjugate to (12) for all i, j . Furthermore, by considering $\rho(ij)^2 = \rho((ij)^2) = \rho(e) = \text{id}$, $\rho(ij) = \pm \text{id}$. Now, by recalling that $\sigma = \tau\sigma'\tau^{-1} \iff \text{sign}(\sigma) = \text{sign}(\sigma')$, and the fact that every permutation can be represented as a product of transpositions, either, $\rho(\sigma) = \text{sign}(\sigma) \cdot \text{id}$ or $\rho(\sigma) = \text{id}$. Thus, there exists exactly two 1-dimensional representation up to isomorphism.

2.4 Abelianisation

We have so far showed that if G is abelian, then every finite dimensional representation of G must be 1-dimensional (and in fact, we may drop the finite dimensional condition if G is finite). Now we would like to reduce the study of 1-dimensional representations of any group G to that of an abelian group.

Definition 2.18 (Commutator). Given a group G , the commutator subgroup is the subgroup $[G, G]$ generated by $[g, h] := ghg^{-1}h^{-1}$ for all $g, h \in G$.

Proposition 2.15. Given a group G , then

- $[G, G] \trianglelefteq G$ ($[G, G]$ is a normal subgroup of G);
- $G/[G, G]$ is abelian;
- for a normal subgroup $N \trianglelefteq G$, G/N is abelian if and only if $[G, G] \leq N$.

Proof.

- For all $g, h_1, h_2 \in G$, we have

$$g[h_1, h_2]g^{-1} = [gh_1g^{-1}, gh_2g^{-1}] \in [G, G].$$

- Denote $\bar{g} := g[G, G]$, then $\bar{g}\bar{h} = gh[G, G]$, now since $h^{-1}g^{-1}hg \in [G, G]$, we have

$$\bar{g}\bar{h} = gh[G, G] = gh(h^{-1}g^{-1}hg)[G, G] = hg[G, G] = \bar{h}\bar{g}.$$

- If G/N is abelian, then

$$gNhN = hNgN \implies N = gNhNg^{-1}h^{-1}N = ghg^{-1}h^{-1}N,$$

thus, $ghg^{-1}h^{-1} \in N$ and so, $[G, G] \leq N$.

□

Definition 2.19 (Abelianisation). The abelianisation of a group G is the abelian group $G_{ab} := G/[G, G]$.

We note that as for all normal subgroup N for which G/N is abelian, we have $[G, G] \trianglelefteq N \trianglelefteq G$, by the third isomorphism theorem, we have

$$\frac{G_{ab}}{N/[G, G]} \equiv \frac{G/[G, G]}{N/[G, G]} \cong \frac{G}{N}.$$

Proposition 2.16. Let A be an abelian group, the map

$$\text{Hom}(G_{ab}, A) \rightarrow \text{Hom}(G, A) : \phi \mapsto \phi \circ q_{ab},$$

is a bijection, where $q_{ab} : G \mapsto G_{ab}$ is the quotient map.

In other words, every homomorphism $\psi : G \rightarrow A$ uniquely corresponds to the homomorphism $\phi : G_{ab} \rightarrow A$ such that $\psi = \phi \circ q_{ab}$.

With this proposition, we see that for all normal subgroups $N \trianglelefteq G$ such that G/N is abelian, we have the following diagram.

$$\begin{array}{ccc} G & \xrightarrow{q_N} & G/N \\ q_{ab} \downarrow & \nearrow \exists! & \\ G_{ab} & & \end{array}$$

Proof. Suppose that $\phi : G \rightarrow A$ is a homomorphism, then $\phi([g, h]) = \phi(ghg^{-1}h^{-1}) = e_A$, and thus, $[G, G] \leq \ker \phi$. Hence, using the universal property of quotient, there exists

$$\bar{\phi} : G_{ab} \rightarrow A : g[G, G] = \phi(g).$$

By construction, $\bar{\phi} \circ q_{ab} = \phi$, and hence, the map is surjective.

On the other hand, if $\phi \circ q_{ab} = \psi \circ q_{ab}$, then for all $g \in G$, $\phi(g) = (\phi \circ q_{ab})(g) = (\psi \circ q_{ab})(g) = \psi(g)$ and so $\phi = \psi$. Thus, the map is bijective as required. \square

Corollary 3.5. If $|G_{ab}| < \infty$, then the number of 1-dimensional representations of G equals $|G_{ab}|$.

Proof. Follows as the 1-dimensional representations of G are $\text{Hom}(G, GL_1(\mathbb{C}))$ which bijects $\text{Hom}(G_{ab}, GL_1(\mathbb{C}))$, and as G_{ab} is abelian, it has $|G_{ab}|$ number of 1-dimensional representations. \square

Corollary 3.6. If $|G| < \infty$, then the number of 1-dimensional representations of G divides $|G|$.

Proof. Follows as $|G_{ab}| \mid |G|$ by Lagrange's theorem. \square

In some sense we have found a bijection between G_{ab} and the set of 1-dimensional representations of G . However, while G_{ab} is a group, the 1-dimensional representations of G are not. In fact, there is a natural group structure on the 1-dimensional representations of G , and for G_{ab} finite, the two groups are isomorphic (exercise).

Proposition 2.17. If G is simple nonabelian, then $G_{ab} = \{e\}$.

Proof. Clear as the only normal subgroups of a simple groups are the trivial subgroup or the entire group. \square

Definition 2.20 (Perfect). A group G is perfect if $[G, G] = G$ (or equivalently $G_{ab} = \{e\}$).

From the above proposition, we see that simple nonabelian implies perfect. Furthermore, G is perfect implies all 1-dimensional representations of G are trivial. In the case the G is finite, the converse is also true.

2.5 Decomposition of Representations

2.5.1 Regular Representation

Recall that for linear maps, the space of all linear maps between two vector spaces form a linear map and we have the following isomorphisms.

Lemma 2.2.

$$\text{Hom}(V, W_1 \oplus W_2) \cong \text{Hom}(V, W_1) \oplus \text{Hom}(V, W_2),$$

and similarly,

$$\text{Hom}(V_1 \oplus V_2, W) \cong \text{Hom}(V_1, W) \oplus \text{Hom}(V_2, W).$$

Proof. Clear using the natural bijections. \square

Similarly to the situation for vector spaces, the space of representations also form a vector space and similar isomorphisms hold. In particular,

$$\mathrm{Hom}_G(V, W_1 \oplus W_2) \cong \mathrm{Hom}_G(V, W_1) \oplus \mathrm{Hom}_G(V, W_2),$$

and

$$\mathrm{Hom}_G(V_1 \oplus V_2, W) \cong \mathrm{Hom}_G(V_1, W) \oplus \mathrm{Hom}_G(V_2, W),$$

where the space $(\mathrm{Hom}_G(V, W), \rho_{\mathrm{Hom}(V, W)})$ is defined such that

$$\rho_{\mathrm{Hom}(V, W)}(g)(\phi) = \rho_W(g) \circ \rho \circ \rho_V(g)^{-1}.$$

If G is finite, By Maschke's theorem, $\mathbb{C}[G]$ is finite dimensional, and so, $\mathbb{C}[G]$ is always decomposable into irreducible representations. We will now prove some properties about this decomposition.

Proposition 2.18. Let V_1, \dots, V_m be irreducible representations that are non-isomorphic such that

$$\mathbb{C}[G] \cong V_1^{r_1} \oplus \dots \oplus V_m^{r_m},$$

where $W^k = W \oplus \dots \oplus W$ k -times. Then, $\dim V_i = r_i$.

Proof. Recall that $\mathrm{Hom}_G(\mathbb{C}[G], V) \cong V$ by the bijection $\phi \mapsto \phi(e)$. So, by this and the above isomorphism,

$$V_i \cong \mathrm{Hom}_G(\mathbb{C}[G], V_i) \cong \bigoplus_{j=1}^m \mathrm{Hom}_G(V_j, V_i)^{r_j}.$$

By Schur's lemma, for all $i \neq j$, we have $\mathrm{Hom}_G(V_i, V_j) = 0$ and so,

$$\bigoplus_{j=1}^m \mathrm{Hom}_G(V_j, V_i)^{r_j} \cong (\mathbb{C} \cdot \mathrm{Id}_{V_i})^{r_i} \cong \mathbb{C}^{r_i}.$$

Thus, we have $\dim V_i = r_i$. □

Corollary 3.7. Let V_1, \dots, V_m be irreducible representations that are non-isomorphic such that

$$\mathbb{C}[G] \cong V_1^{r_1} \oplus \dots \oplus V_m^{r_m}.$$

Then, $r_i = 1$ for all i if G is abelian.

As we shall see, converse is also true.

Corollary 3.8. Let V_1, \dots, V_m be irreducible representations that are non-isomorphic such that

$$\mathbb{C}[G] \cong V_1^{r_1} \oplus \dots \oplus V_m^{r_m},$$

then

$$|G| = \sum_{i=1}^m (\dim V_i)^2.$$

Proof.

$$|G| = \dim \mathbb{C}[G] = \dim(V_1^{r_1} \oplus \dots \oplus V_m^{r_m}) = \dim(V_1^{\dim V_1} \oplus \dots \oplus V_m^{\dim V_m}) = \sum_{i=1}^m (\dim V_i)^2.$$

□

This is the sum of squares formula though it provided that every irreducible representation of G is isomorphic to exactly one of the V_i .

Proposition 2.19. Let V_1, \dots, V_m be irreducible representations that are non-isomorphic such that

$$\mathbb{C}[G] \cong V_1^{r_1} \oplus \dots \oplus V_m^{r_m}.$$

Then for all irreducible representations W of G , there exists uniquely i such that $W \cong V_i$.

Proof. By assumption $V_i \not\cong V_j$ for $i \neq j$ and so, it remains to show W must be isomorphic at some V_i . Suppose otherwise, then,

$$W \cong \text{Hom}_G(\mathbb{C}[G], W) \cong \bigoplus_i \text{Hom}_G(V_i, W) = 0,$$

by Schur's lemma, which is a contradiction.

□

Corollary 3.9. For non-trivial G , every irreducible representation has dimension strictly less than $\sqrt{|G|}$.

Proof. Given (V, ρ) a non-trivial representation,

$$|G| = \dim \mathbb{C}[G] = \dim(\mathbb{C} \oplus V^{\dim V} \oplus \dots) \geq \dim(\mathbb{C} \oplus V^{\dim V}) = 1 + (\dim V)^2.$$

□

2.5.2 Revisiting Maschke's Theorem

Definition 2.21 (G -invariant Subspace). Given a representation (V, ρ_V) of g , then the G -invariant subspace of V is

$$V^G := \{v \in V \mid \rho_V(g)(v) = v, \forall g \in G\}.$$

A useful note is that, V^G is the intersection of all eigenspaces of $\rho_V(g)$ of eigenvalue 1 for all g .

Lemma 2.3. $V^G \subseteq V$ is the largest trivial subrepresentation of V .

Proof. V^G is a trivial subrepresentation as it sends every element of V^G to itself and thus, $\rho_{V^G}(g) = \text{Id}_{V^G}$ for all $g \in G$. Lastly, if $W \subseteq V$ is a trivial subrepresentation, for all $v \in W$, $\rho_W(g)(v) = \text{Id}_W v = v$ for all $g \in G$, and so $v \in V^G$ and hence, $W \subseteq V^G$. □

Definition 2.22 (Averaging Map). If G is finite and (V, ρ_V) is a representation of G , then the averaging map is the function

$$\text{avg} : V \rightarrow V : v \mapsto \frac{1}{|G|} \sum_{g \in G} \rho_V(g)(v).$$

Proposition 2.20. The averaging map is a G -linear projection with the image V^G .

Proof. Clearly, $\text{Im}(\text{avg}) \subseteq V^G$ since for all $h \in G, v \in V$,

$$\rho(h)(\text{avg}(v)) = \rho(h) \left(\frac{1}{|G|} \sum_{g \in G} \rho(g)(v) \right) = \frac{1}{|G|} \sum_{g \in G} \rho(hg)(v) = \frac{1}{|G|} \sum_{g \in G} \rho(g)(v) = \text{avg}(v).$$

Furthermore, as $\text{avg}|_{V^G} = \text{Id}_{V^G}$, we have $\text{Im}(\text{avg}) = V^G$ and thus, avg is a projection. Finally, by the same calculation, we have

$$\rho(h)(\text{avg}(v)) = \frac{1}{|G|} \sum_{g \in G} \rho(hg)(v) = \frac{1}{|G|} \sum_{g \in G} \rho(gh)(v) = \frac{1}{|G|} \sum_{g \in G} \rho(g)(\rho(h)(v)) = \text{avg}(\rho(h)(v)),$$

which shows avg is a G -linear map. \square

With this proposition, we obtain that $V = \ker(\text{avg}) \oplus V^G$ with $\ker(\text{avg})$ being a subrepresentation with no G -invariant vectors, i.e. $\ker(\text{avg})^G = \{0\}$. With these definitions in mind, let us revisit Maschke's theorem.

Proposition 2.21. $\text{Hom}_G(V, W) = \text{Hom}(V, W)^G$.

Proof. Definition check. \square

Corollary 3.10. The map

$$\text{avg} : \text{Hom}(V, W) \rightarrow \text{Hom}(V, W)^G = \text{Hom}_G(V, W)$$

is a G -linear projection.

Thus, with this corollary, we see that the averaging map provides a (G -linear) map between $\text{End}(V)$ and $\text{End}_G(W)$. Nonetheless, to obtain Maschke's theorem, it remains to show that it avg maps linear projections to G -linear projections (with the same image).

2.5.3 Adjoint Representation

Consider V_1, \dots, V_m be all irreducible representations (up to isomorphism) of G with $|G|$. Then, we may define the map

$$G \rightarrow \bigoplus_{i=1}^m \text{End}(V_i) : g \mapsto (\rho_{V_1}(g), \dots, \rho_{V_m}(g)).$$

Linearly extending, we obtain a map $\phi : \mathbb{C}[G] \rightarrow \bigoplus \text{End}(V_i)$. Then, by the sum of squares formula, since $\dim(\text{End}(W)) = (\dim W)^2$, the source and target of ϕ have the same dimension.

Proposition 2.22. The map $\phi : \mathbb{C}[G] \rightarrow \bigoplus \text{End}(V_i)$ is a linear isomorphism and is G -linear with respect to the adjoint representation.

Proof. It suffices to show G -linearity. For all $h \in G$, we have

$$\begin{aligned} \phi(\rho_{ad}(g)(h)) &= \phi(ghg^{-1}) = (\rho_{V_1}(ghg^{-1}), \dots, \rho_{V_m}(ghg^{-1})) \\ &= (\rho_{\text{End}(V_1)}(g)(\rho_{V_1}(h)), \dots, \rho_{\text{End}(V_m)}(g)(\rho_{V_m}(h))) \\ &= \rho(g)(\phi(h)). \end{aligned}$$

□

Thus, we have found an isomorphism $\mathbb{C}[G]_{ad} \cong \bigoplus \text{End}(V_i)$ and thus, taking the dimension of both sides, we recover the sum of squares formula $|G| = \sum \dim(V_i)^2$. In particular, we have replaced an equality by an isomorphism and in general, this process is called “categorification”.

Continuing with V_1, \dots, V_m as the irreducible representations of G , $|G| < \infty$ up to isomorphism, we have the following corollaries.

Corollary 3.11. Since,

$$\mathbb{C}[G]_{ad} \cong \bigoplus_{i=1}^m \text{End}(V_i).$$

By taking G -invariant subspaces, we have

$$\mathbb{C}[G]_{ad}^G \cong \bigoplus_{i=1}^m \text{End}(V_i)^G = \bigoplus \text{End}_G(V_i) = \bigoplus \mathbb{C} \cdot \text{Id}_{V_i} \cong \mathbb{C}^m$$

by Schur’s lemma.

Proposition 2.23. $(\mathbb{C}[G], \rho_{ad})^G$ have a basis $f_1, \dots, f_{m'}$ given by

$$f_i = \sum_{g \in \mathcal{C}_i} g,$$

where $\mathcal{C}_1, \dots, \mathcal{C}_{m'}$ are the conjugacy classes of G .

Proof. Follows by considering $\sum a_g g \in \mathbb{C}[G]_{ad}^G \iff a_h = a_{ghg^{-1}}$ for all $g, h \in G$. □

Corollary 3.12. The number of conjugacy classes of G equals the number of irreducible representation up to isomorphisms.

Proof. Follows by taking the dimensions on both sides of the isomorphism $\mathbb{C}[G]_{ad}^G \cong \mathbb{C}^m$. □

2.6 Tensor Product and Dual Representations

We will in the section recall tensor product of vector spaces and extend the notion of tensor products to representations.

2.6.1 Tensor Product of Vector Spaces

In essence, similar to direct sums, the tensor product of two vector spaces in some sense combine them into a larger vector space. In particular, while (external) direct sums “glue” the vectors of the two spaces, the tensor product combined the coefficients of each vectors of the two spaces pairwise.

Definition 2.23 (Free Vector Space). Let S be a set and \mathbb{F} be a field. Then the \mathbb{F} -free vector space over S is the set given by

$$\mathbb{F}[S] := \left\{ \sum_{s \in S} a_s s \mid |\text{supp}(a)| < \infty \right\}.$$

We note that we have already seen this definition in the context of monoid algebras. The free vector space is equipped with the natural notion of addition and scalar multiplication and forms a vector space over \mathbb{F} .

Again, $s \in S$ corresponds to the elements of the free vector space with coefficients $a_s = 1$ and $a_r = 0$ for all $r \neq s$, and in that sense, S is a basis of $\mathbb{F}[S]$. Thus, with this definition, we may consider the free vector space of $V \times W$. It is clear that $\mathbb{F}[V \times W]$ has a basis of $V \times W$, and so $\mathbb{F}[V \times W]$ is huge in the sense that

$$\dim \mathbb{F}[V \times W] = |V \times W|.$$

In some sense, the construction of the free vector space forgets the vector space structure of V and W (am I correct in saying it is a forgetful functor?). In particular, we note that for $v_1, v_2 \in V, w \in W$, $(v_1, w) +_{\mathbb{F}[V \times W]} (v_2, w)$ corresponds to the function which maps (v_1, w) and (v_2, w) to 1 and 0 otherwise, and thus, $(v_1, w) +_{\mathbb{F}[V \times W]} (v_2, w) \neq (v_1 + v_2, w)$.

This, is however not what we want and so we will quotient it by some subspace.

Definition 2.24 (Tensor Product). Let V, W be vector spaces over the field \mathbb{F} and define $B(V \times W)$ a subspace of $\mathbb{F}[V \times W]$ by

$$\begin{aligned} B(V \times W) = \text{span}\{ & (v_1 + v_2, w) - (v_1, w) - (v_2, w); \\ & (v, w_1 + w_2) - (v, w_1) - (v, w_2); \\ & (\lambda v, w) - \lambda(v, w); \\ & (v, \lambda w) - \lambda(v, w) \mid v, v_1, v_2 \in V, w, w_1, w_2 \in W, \lambda \in \mathbb{F} \}. \end{aligned}$$

Then the tensor product $V \otimes W$ is simply

$$V \otimes W = \mathbb{F}[V \times W] / B(V \times W).$$

We denote the image of $(v, w) \in \mathbb{F}[V \times W]$ under the quotient map $\mathbb{F}[V \times W] \rightarrow V \otimes W$ by $v \otimes w$.

Proposition 2.24. For V, W vector spaces over the field \mathbb{F} , for all $v, v_1, v_2 \in V, w, w_1, w_2 \in W, \lambda \in \mathbb{F}$, we have

- $(v_1 + v_2) \otimes w = v_1 \otimes w + v_2 \otimes w;$
- $v \otimes (w_1 + w_2) = v \otimes w_1 + v \otimes w_2;$

- $(\lambda v) \otimes w = \lambda(v \otimes w)$;
- $v \otimes (\lambda w) = \lambda(v \otimes w)$.

Proof. By definition of the quotient. \square

Theorem 4 (Universal Property). Let V, W, Z be vector spaces, then there exists a bilinear map $F : V \times W \rightarrow V \otimes W$ such that for all bilinear maps $\alpha : V \times W \rightarrow Z$, there exists a unique linear map $\tilde{\alpha} : V \otimes W \rightarrow Z$ such that $\alpha = \tilde{\alpha} \circ F$.

Proof. Let α be a bilinear map, and we can define $\bar{\alpha}$ as the linear extension of α such that

$$\bar{\alpha} : \mathbb{F}[V \times W] \rightarrow Z : \sum_{i=1}^n a_i(v_i, w_i) \mapsto \sum_{i=1}^n a_i \alpha(v_i, w_i).$$

Since α is bilinear, we have $B(V \times W) \subseteq \ker \bar{\alpha}$. Thus, by the universal property of the quotient, there exists a unique $\tilde{\alpha} : V \otimes W \rightarrow Z$ such that $\tilde{\alpha} \circ q = \bar{\alpha}$. \square

One might imagine the universal property as the following commuting diagram.

$$\begin{array}{ccc} V \times W & \xrightarrow{\alpha} & Z \\ F \downarrow & \nearrow \tilde{\alpha} & \\ V \otimes W & & \end{array}$$

In particular, we have the diagram

$$\begin{array}{ccccc} V \times W & \xleftarrow{\iota} & \mathbb{F}[V \times W] & \xrightarrow{q} & V \otimes W \\ & \searrow \alpha & \downarrow \tilde{\alpha} & \nearrow \tilde{\alpha} & \\ & & Z & & \end{array}$$

and so we may simply $F = q \circ \iota$ which is bilinear.

Thus, with the universal property, we have obtained a bijection between the set of bilinear maps from $V \times W \rightarrow Z$ and the set of linear maps between $V \otimes W \rightarrow Z$.

Proposition 2.25. The universal property determines $V \otimes W$ uniquely up to isomorphism, i.e. if Z is a vector space satisfying the universal property of $V \otimes W$, then $Z \cong V \otimes W$.

Proof. Exercise. \square

Proposition 2.26. Let $(v_i)_{i \in I}$ be a basis of V , and $(w_j)_{j \in J}$ be a basis of W . Then, $(v_i \otimes w_j)_{i \in I, j \in J}$ is a basis of $V \otimes W$.

Proof. Exercise (Hint: to show linear independence, consider the bilinear map $B_{nk} : V \times W \rightarrow \mathbb{F} : (\sum \lambda_i v_i, \sum \mu_j w_j) \mapsto \lambda_n \mu_k$ for all n, k). \square

Proposition 2.27. There is a canonical linear injection

$$V^* \otimes W \rightarrow \text{Hom}(V, W),$$

and this is an isomorphism if V is finite dimensional.

Proof. Define

$$T : V^* \times W \rightarrow \text{Hom}(V, W) : (f, w) \mapsto (v \mapsto f(v)w).$$

It is easy to see that T is bilinear and so, by the universal property, there exists a unique linear map $\tilde{T} : V^* \otimes W \rightarrow \text{Hom}(V, W)$ such that $\tilde{T}(f \otimes w) = T(f, w)$. Now, if $f \otimes w \in \ker \tilde{T}$, we have either $f = 0$ or $w = 0$, and so $f \otimes w = 0$. Thus, $\ker \tilde{T} = \{0\}$ and hence, it is an injection.

In the case that V is finite dimensional, we have

$$\dim(V^* \otimes W) = \dim V^* \dim W = \dim V \dim W = \dim(\text{Hom}(V, W)),$$

and so T is an isomorphism by a dimensional argument. \square

Corollary 4.1. For V finite dimensional, we have

$$V \otimes W \cong V^{**} \otimes W \cong \text{Hom}(V^*, W).$$

Proposition 2.28. $\mathbb{F} \otimes W \cong W$.

Proof. Exercise. \square

Lemma 2.4. Given linear maps $T_1 : V \rightarrow U_1, T_2 : W \rightarrow U_2$, we have

$$T_1 \otimes T_2 : V \otimes W \rightarrow U_1 \otimes U_2 : v \otimes w \mapsto T_1(v) \otimes T_2(w),$$

is a linear map. Furthermore, if T_i, S_i for $i = 1, 2$ are linear maps on appropriate domains and codomains,

$$(T_1 \otimes T_2) \circ (S_1 \otimes S_2) = (T_1 \circ S_1) \otimes (T_2 \circ S_2).$$

Proof. Easy checks using the universal property. \square

2.6.2 Tensor Product of Representations

In representation theory, we may also consider the tensor product of representations. In particular, if (V, ρ_V) and (W, ρ_W) are representations, then we define

$$(V \otimes W, \rho_{V \otimes W} := g \mapsto \rho_V(g) \otimes \rho_W(g)),$$

to be the tensor product of the representations. We note that $\rho_V(g) \otimes \rho_W(g) \in GL(V \otimes W)$ for all g by lemma 2.4 and so the representation is well-defined.

In the case that $V = \mathbb{C}$, we have the representation $\rho_V : G \mapsto GL_1(\mathbb{C}) \cong \mathbb{C}^\times$ is simply a multiplication by some scalar $\rho \neq 0$. Thus, $\rho_{\mathbb{C} \otimes W}(g) = \rho \rho_W(g)$, and

$$(\mathbb{C} \otimes W, \rho_{\mathbb{C} \otimes W}) \cong (W, \rho \rho_W).$$

Furthermore, if $W = \mathbb{C}$ as well, then we have $(\mathbb{C}, \rho \otimes \rho') \cong (\mathbb{C}, \rho \rho')$.

N.B. omitted some exercises which I'm confused about.

Definition 2.25 (Dual Representation). Given a representation (V, ρ_V) , we define the dual representation to be the representation (V^*, ρ_{V^*}) where V^* is the dual space of V and

$$\rho_{V^*}(g)(\phi) = \phi \circ \rho_V(g)^{-1},$$

for all $\phi \in V^*$, $g \in G$.

We note that the inverse in the definition is required since

$$\rho_{V^*}(gh)(\phi) = \rho_{V^*}(g) \circ \rho_{V^*}(h)(\phi) = \phi \circ \rho_V(h^{-1}) \circ \rho_V(g^{-1}) = \phi \circ \rho_V(h^{-1}g^{-1}) = \phi \circ \rho_V(gh)^{-1}.$$

In the case we are working with finite dimensional representations, given a basis $B = \{v_1, \dots, v_n\}$ of V , we have a dual basis $D = \{f_1, \dots, f_n\}$ of V^* given by $f_i(v_j) = \delta_{ij}$. Then, the (j, i) -th entry of $[\rho_{V^*}(g)]_D$ is

$$\rho_{V^*}(g)(f_i)(v_j) = f_i(\rho_V(g^{-1})(v_j)).$$

On the other hand, the (i, j) -th entry of $[\rho_V(g^{-1})]_B$ is $f_i(\rho_V(g^{-1})(v_j))$ and so,

$$[\rho_{V^*}(g)]_D = [\rho_V(g^{-1})]_B^T = ([\rho_V(g)]_B^{-1})^T.$$

A similar relation can be established for the matrix form of the tensor product. Let $B = \{v_1, \dots, v_m\}$ be a basis of V and $C = \{w_1, \dots, w_n\}$ be a basis of W . Then, $D := \{v_i \otimes w_j\}$ form a basis of $V \otimes W$. Let $g \in G$ and $M := [\rho_V(g)]_B$, $N = [\rho_W(g)]_C$. Then,

$$\begin{aligned} \rho_{V \otimes W}(g)(v_k \otimes w_l) &= \rho_V(g)(v_k) \otimes \rho_W(g)(w_l) = \sum_i M_{ik} v_i \otimes \sum_j N_{jl} w_j \\ &= \sum_{i,j} M_{ik} v_i \otimes N_{jl} w_j = \sum_{i,j} M_{ik} N_{jl} v_i \otimes w_j. \end{aligned}$$

Thus, the matrix representation of $\rho_{V \otimes W}(g)$ is

$$[\rho_{V \otimes W}(g)]_{B \otimes C} = [M_{ik} N_{jl}]_{(i,j), (k,l)}.$$

Note that the rows are indexed by pairs $(i, j) \in I \times J$ and the columns by $(k, l) \in I \times J$.

This matrix operation is known as the Kronecker product, in particular, the Kronecker product of matrices $[a_{ik}]$ and $[b_{jl}]$ is

$$[a_{ik}] \otimes [b_{jl}] := [a_{ik} b_{jl}]_{(i,j), (k,l)}.$$

2.6.3 External Tensor Product

So far we have seen methods of constructing new representations of G using existing representations of G with the tensor product. It turns out this procedure can be applied to smaller groups to obtain representations on a larger group.

Given $(V, \rho_V), (W, \rho_W)$ representations of G , we note that $V \otimes W$ actually provides a representation of $G \times G$ by taking $\rho_V(g) \otimes \rho_W(h)$ for $(g, h) \in G \times G$. Let us denote this representation by $\rho_{V \boxtimes W}$.

Definition 2.26 (External Tensor Product). Let (V, ρ_V) be a representation of G and (W, ρ_W) be a representation of H . Then $(V \otimes W, \rho_{V \otimes W})$ is a representation of $G \times H$ where

$$\rho_{V \otimes W}(g, h) = \rho_V(g) \otimes \rho_W(h).$$

Proposition 2.29. $(V \otimes W, \rho_{V \otimes W})$ is irreducible if and only if V and W are irreducible. Furthermore, if G and H are finite, these are the only irreducible representations of $G \times H$ up to isomorphism.

Proof. Omitted. □

3 Restriction and Coinduction

We have already used the following definition though it is useful to introduce a notation for it.

Definition 3.1 (Resetricted Representation). Given a subgroup $H < G$ and a representation (V, ρ_V) of G , the restricted representation $\text{Res}_H^G(V)$ is the representation of H defined by $(V, \rho_v \circ i)$ where i is the inclusion map from H to G .

As the underlying vector space remains the same, we have $\dim V = \dim \text{Res}_H^G(V)$.

Conversely, we would like to obtain a representation of G from a representation of H . This process is known as induction and the resulting representation is called the (co)induced representation.

Definition 3.2 (Coinduced Representation). Let $H < G$ be a subgroup and (V, ρ_V) be a representation of H . Then, the coinduced representation $\text{coInd}_H^G(V)$ is defined as

$$\text{coInd}_H^G(V) := \{f : G \rightarrow V \mid f(hg) = \rho_V(h)f(g), \forall g \in G, h \in H\},$$

with the action of G given by $(g \cdot \phi)(g') := \phi(g'g)$.

We see that $\text{coInd}_H^G(V)$ are functions from G to V which are H -invariant. Equivalently, the coinduced representation can be defined by $\text{coInd}_H^G(V) = \text{Hom}_H(\mathbb{C}[G], V)$. Unlike the restricted representation, the coinduced representation does not fix the dimension.

Proposition 3.1. Denoting $H \backslash G$ the set of right cosets of H in G , the map

$$\Psi : \text{Fun}(H \backslash G, V) \rightarrow \text{coInd}_H^G(V) : \phi \mapsto (hg_i \mapsto \rho_V(h)\phi(Hg_i))$$

is a linear isomorphism.

Proof. Definition check. □

Corollary 4.2. Let $[G : H]$ be the index of the subgroup H , then

$$\dim \text{coInd}_H^G(V) = [G : H] \dim V.$$

Proof. If $[G : H] = \infty$ then both sides of the equation are infinite. Suppose that $[G : H] = n < \infty$, then by the above isomorphism, we have $\dim \text{coInd}_H^G(V) = \dim \text{Fun}(H \backslash G, V) = \dim V^n = [G : H] \dim V$. □

Definition 3.3. Let X be a nonempty set and let $x \in X$. Then we define $V(x) \subseteq \text{Fun}(X, V)$ be the subspace of functions which have value zero on every element of X except x .

Proposition 3.2. $V(x) \cong V$, $\bigoplus_{x \in X} V(x) \subseteq \text{Fun}(X, V)$ which becomes an equality for X finite, and $\text{Fun}(X, V) \cong V^{|X|}$.

4 Character Theory

Character theory is the study of the traces of finite dimensional representations. In particular, character theory study the representations by forgetting the vector space themselves. To support this, we observe that the trace function is invariant under isomorphisms and thus, will play a fundamental role in our definitions.

Definition 4.1 (Character). The character of a representation $(V, \rho : G \rightarrow V)$ is the function $\chi_\rho : G \rightarrow \mathbb{C} : g \mapsto \text{tr}(\rho(g))$.

When there is no confusion, we write χ_V for χ_{ρ_V} .

We recall to that the trace defined on general finite dimensional vector spaces can be found by making a choice of basis and finding the trace of the specific matrix representation. As the trace is independent of the choice of basis, this definition is well-defined.

This definition however is inelegant as we were required to make a choice of basis. The choice can be avoided by observing that $\text{Hom}(V, V) \cong V^* \otimes V$, and there exists a natural map

$$V^* \otimes V \rightarrow \mathbb{C} : f \otimes v \mapsto f(v).$$

Then, composing the two maps, one can show that this is indeed the trace function.

Proposition 4.1. If G is a finite group, then given $(V, \rho_V), (W, \rho_W)$ representations of G , we have $\chi_{\rho_V} = \chi_{\rho_W}$ if and only if $(V, \rho_V) \cong (W, \rho_W)$.

Proof. The backward direction is trivial by choosing a basis while the backwards direction will be proved later in the course. \square

Thus, classifying characters will also classify representations up to isomorphism.

Proposition 4.2. The character of the permutation representation maps g to the number of fixed points of g .

Proof. Exercise. \square

4.1 Class Function

Definition 4.2 (Class Function). A class function $f : G \rightarrow \mathbb{C}$ is a function such that $f(ghg^{-1}) = f(h)$ for all $g, h \in G$.

We denote $\text{Fun}_{cl}(G, \mathbb{C}) \subseteq \mathbb{C}^G = G \rightarrow \mathbb{C}$ the set of class functions.

We observe that if we quotient G by the equivalence relation of conjugacy (note that this quotient is not a group), the class function is a function satisfying the universal property of this quotient.

As remarked in the definition of the free vector space, the set of functions from $X \rightarrow \mathbb{C}$ is closely related to the free vector space $\mathbb{C}[X]$. In particular, we have the embedding

$$\sum a_x x \mapsto (x \mapsto a_x) : \mathbb{C}[X] \rightarrow \mathbb{C}^X,$$

and in the case that X is finite, this map is an isomorphism.

Recall that given a group action $G \times X \rightarrow X$, we may extend this linearly to become a group representation of G with $(\mathbb{C}[X], \rho_{\mathbb{C}[X]})$. A similar process can be applied to \mathbb{C}^X by defining

$$g \cdot f \mapsto (x \mapsto f(g^{-1} \cdot x)) : G \times \mathbb{C}^X \rightarrow \mathbb{C}^X.$$

We note that the inverse is required since for $g_1, g_2 \in G$, we have

$$(g_1 \cdot (g_2 \cdot f))(x) = (g_2 \cdot f)(f(g_1^{-1} \cdot x)) = f(g_2^{-1} g_1^{-1} \cdot x) = f((g_1 g_2)^{-1} \cdot x) = (g_1 g_2 \cdot f)(x).$$

In the case that $X = G$, we again have the 3 representations on \mathbb{C}^X ,

- left regular $(g \cdot_L f)(h) = f(g^{-1}h)$;
- right regular $(g \cdot_R f)(h) = f(hg)$;
- adjoint $(g \cdot_{ad} f)(h) = f(g^{-1}hg)$.

We will mainly only use the adjoint representation in this section.

Proposition 4.3. $\text{Fun}_{cl}(G, \mathbb{C}) = (\mathbb{C}^X)^{G_{ad}}$, i.e. the set of class functions equals to the G -invariant subspace of \mathbb{C}^X with respect to the adjoint representation.

Proof. Unfold the definitions. □

By the property of the trace, it is clear that characters are class functions, and thus, we have the chain of subsets

$$\{\text{Characters}\} \subseteq \text{Fun}_{cl}(G, \mathbb{C}) = (\mathbb{C}^X)^{G_{ad}} \subseteq \mathbb{C}^X.$$

In the case that G is finite, as mentioned before, we have the isomorphism $(\mathbb{C}^X)^{G_{ad}} \cong \mathbb{C}[G]^{G_{ad}}$ where the dimension of the latter is the number of conjugacy classes. Hence the number of irreducible representations equal $\dim(\mathbb{C}^X)^{G_{ad}}$. Thus, the following proposition is motivated.

Definition 4.3. An irreducible character is a character of an irreducible representation.

Proposition 4.4. The irreducible characters form a basis for the set of class functions. In fact, we will define an inner product on this space and show that this basis is orthonormal.

This proposition immediately implies $(V, \rho_V) \not\cong (W, \rho_W)$ implies $\chi_V \neq \chi_W$ since if otherwise, we have found two character linearly dependent with each other.

Lemma 4.1. Let $T \in GL(V)$ such that $T^n = \text{id}_V$ for some $n \geq 1$, then T is diagonalisable with eigenvalues being the n -roots of unity.

Proof. Follows by considering the minimal polynomial, in particular the primary decomposition theorem.

Alternatively using group representation theory, we note that $\langle T \rangle$ form a finite cyclic group under composition, and so the representation (V, ρ_V) on $\langle T \rangle$ where $\rho_V(T) = T$ is decomposable into 1-dimensional subrepresentations. Hence, $\rho_V(T) = T$ has an eigenbasis and so is diagonalisable. Finally, as $T^n = \text{id}_V$, we have the eigenvalues being the n -roots of unity. □

Proposition 4.5. Let $g \in G$ be an element of finite order and let (V, ρ_V) be a finite dimensional representation. Then,

- $\chi_V(g^{-1}) = \overline{\chi_V(g)}$;
- $|\chi_V(g)| \leq \dim V$ with equality if and only if $\rho_V(g) = \lambda \text{id}_V$ for some $\lambda \in \mathbb{C}$;
- $\chi_V(e) = \dim V$.

Proof. $g \in G$ be an element of finite order. Then, if the eigenvalues of $\rho_V(g)$ are $\lambda_1, \dots, \lambda_n$,

- if the eigenvalues of $\rho_V(g)$ are $\lambda_1, \dots, \lambda_n$, the eigenvalues of $\rho_V(g^{-1})$ are $\lambda_1^{-1}, \dots, \lambda_n^{-1}$. But, $g^{|g|} = 1$ and so $\lambda_i^{|g|} = 1$ implying $\lambda_i^{-1} = \overline{\lambda_i}$. Thus, the equality follows as the character is simply the sum of the eigenvalues.
- by the triangle inequality we have

$$|\chi_V(g)| = |\lambda_1 + \dots + \lambda_n| \leq |\lambda_1| + \dots + |\lambda_n| = 1 + \dots + 1 = \dim V.$$

The less equal is an equality if and only if all λ_i points in the same direction on \mathbb{C} , and since $|\lambda_i| = 1$ for all i , the eigenvalues must be the same λ . Hence $\rho_V(g) = \lambda \text{id}_V$.

- clear.

□

Corollary 4.3. $g \in \ker \rho_V \iff \chi_V(g) = \dim V$.

We recall that the tensor product and the direct sum interacts in a way similar to a semiring modulo isomorphisms. In particular, the dimension of a vector space is a semiring homomorphism from the space of vector spaces (quotiented by isomorphism) to the natural numbers, i.e.

$$\dim : \{\text{f.d. vector spaces}\} / \cong \rightarrow \mathbb{N}.$$

Analogously, the character is a homomorphism between the representations of a group and the complex numbers, i.e.

$$\chi : \{\text{representations of } G\} \rightarrow \mathbb{C}.$$

Proposition 4.6. Let $(V, \rho_V), (W, \rho_W)$ be finite dimensional representations of G , then

- $\chi_{V \oplus W} = \chi_V + \chi_W$;
- $\chi_{V \otimes W} = \chi_V \chi_W$;
- $\chi_{V^*}(g) = \overline{\chi_V(g)}$;
- $\chi_{\text{Hom}(V, W)}(g) = \overline{\chi_V(g)} \chi_W(g)$.

where the third and fourth statement requires $g \in G$ to have finite order. In the case g does not have finite order, $\chi_{V^*}(g) = \chi_V(g)^{-1}$ and $\chi_{\text{Hom}(V, W)}(g) = \chi_V(g)^{-1} \chi_W(g)$ still holds.

Proof. Clear by choosing a basis.

□

4.2 Orthogonality of Characters

Recall the definition of a Hermitian inner product (in particular, we will assume linearity with respect to the first argument) and some elementary results about orthogonality.

Proposition 4.7. A set of orthonormal vectors is linearly independent.

Definition 4.4. We define the following inner product $\langle \cdot, \cdot \rangle$ on \mathbb{C}^G such that,

$$\langle f_1, f_2 \rangle = \frac{1}{|G|} \sum_{g \in G} f_1(g) \overline{f_2(g)}.$$

In the case that G is infinite but has a finite measure μ (c.f. Haar measure), then we may define

$$\langle f_1, f_2 \rangle := \frac{1}{\mu(G)} \int_G f_1(g) \overline{f_2(g)} d\mu.$$

The properties of the finite case generalizes provided that G is compact and the measure is invariant under translation, i.e. $\mu(X) = \mu(g \cdot X)$ for all $g \in G, X \subseteq G$ (c.f. Haar's theorem).

Lemma 4.2. Let $T \in \text{End}(U)$ be a linear projection. Then $\dim T(U) = \text{tr}(T)$.

Proof. We have $U = \ker T \oplus T(U)$, and furthermore, we have $T|_{\ker T} = 0$ and $T|_{T(U)} = \text{id}|_{T(U)}$ and thus, $\text{tr}(T) = \text{tr}(T|_{\ker T}) + \text{tr}(T|_{T(U)}) = \dim T(U)$. \square

Theorem 5. Let (V, ρ_V) and (W, ρ_W) be finite dimensional representations of the finite group G . Then,

$$\langle \chi_V, \chi_W \rangle = \dim \text{Hom}_G(V, W).$$

Proof. Recall the averaging map

$$\text{avg} : \text{Hom}(V, W) \rightarrow \text{Hom}(V, W) : \phi \mapsto \frac{1}{|G|} \sum_{g \in G} \rho_{\text{Hom}(V, W)}(g)(\phi)$$

is a G -linear projection with the image $\text{Hom}(V, W)^G = \text{Hom}_G(V, W)$. Now, by considering

$$\text{tr}(\text{avg}) = \frac{1}{|G|} \sum_{g \in G} \chi_{\text{Hom}(V, W)}(g) = \frac{1}{|G|} \sum_{g \in G} \overline{\chi_V(g)} \chi_W(g) = \langle \chi_W, \chi_V \rangle,$$

since $\text{Hom}(V, W) \cong V^* \otimes W$, we have

$$\langle \chi_V, \chi_W \rangle = \overline{\langle \chi_W, \chi_V \rangle} = \overline{\text{tr}(\text{avg})} = \overline{\dim \text{Hom}_G(V, W)}.$$

Thus, as $\dim \text{Hom}_G(V, W) \in \mathbb{N}$, we have $\overline{\dim \text{Hom}_G(V, W)} = \dim \text{Hom}_G(V, W)$ and

$$\langle \chi_V, \chi_W \rangle = \dim \text{Hom}_G(V, W).$$

\square

Corollary 5.1. If V, W are irreducible, then

$$\langle \chi_V, \chi_W \rangle = \begin{cases} 1, & V \cong W, \\ 0, & V \not\cong W. \end{cases}$$

Proof. By Schur's lemma. \square

Corollary 5.2. If V_1, \dots, V_m are irreducible and non-isomorphic representations, then $\chi_{V_1}, \dots, \chi_{V_m}$ are orthonormal.

Corollary 5.3. If V_1, \dots, V_m are all non-isomorphic irreducible representations of (the finite group) G up to isomorphism, their characters form an orthonormal basis of $\text{Fun}_{cl}(G, \mathbb{C})$.

Proof. As all characters are class functions, $\chi_{V_1}, \dots, \chi_{V_m}$ is a linearly independent set of class functions. Now, as the dimension of $\text{Fun}_{cl}(G, \mathbb{C})$ is the number of conjugacy classes of G which equals the number of irreducible representations up to isomorphism, $\chi_{V_1}, \dots, \chi_{V_m}$ is a basis of $\text{Fun}_{cl}(G, \mathbb{C})$ as required. \square

Corollary 5.4. $V \cong W \iff \chi_V = \chi_W$ for G finite.

Proof. It suffices to prove the reverse direction. Suppose $V \not\cong W$, and WLOG. assume V, W are irreducible. Then, $\langle \chi_V, \chi_W \rangle \neq 0$ implying $\chi_V \neq \chi_W$. \square

The inner product also allows us to recover the multiplicities of the irreducible representations. In particular, if $V = V_1^{r_1} \oplus \dots \oplus V_m^{r_m}$, then

$$\langle \chi_V, \chi_{V_i} \rangle = \langle r_1 \chi_{V_1} + \dots + r_m \chi_{V_m}, \chi_{V_i} \rangle = r_i.$$

4.3 Character Table

We have so far found one set of orthonormal basis of $\text{Fun}_{cl}(G, \mathbb{C})$ which are the characters belonging to the irreducible representations. On the other hand, we notice that there is another orthonormal basis of the class functions defined such that, for each conjugacy class C of G , we set

$$\delta_C : G \rightarrow \mathbb{C} : g \mapsto \begin{cases} 1, & g \in C, \\ 0, & g \notin C. \end{cases}$$

Clearly, $\{\delta_C\}$ is orthogonal and there are $\dim \text{Fun}_{cl}(G, \mathbb{C})$ of them, and thus form a basis. Now, to obtain an orthonormal basis, by simply considering

$$\langle \delta_C, \delta_C \rangle = \frac{1}{|G|} \sum_{g \in G} \delta_C(g)^2 = \frac{|C|}{|G|},$$

we see that $\{\sqrt{|G|/|C|} \delta_C\}$ form an orthonormal basis of $\text{Fun}_{cl}(G, \mathbb{C})$.

Thus, we have two sets of orthonormal basis of the class functions and we may ask what is the change of basis matrix between the two. In particular, we see that the change of basis matrix has (i, j) -entry $\sqrt{|C_j|/|G|} \chi_{\rho_i}(g_j)$ where g_j is any element of C_j . Commonly however, we omit the normalization and so define a matrix A such that $A_{ij} = \chi_{\rho_i}(g_j)$ and we refer to this as the character table.

Definition 4.5 (Unitary). A unitary matrix A is a matrix such that $A^{-1} = \overline{A^T}$.

Proposition 4.8. A is unitary if and only if the row of A are orthonormal if and only if the column of A are orthonormal.

Proposition 4.9. A change of basis matrix between two orthonormal bases is unitary.

By the orthogonality of the columns of the character table A , we obtain

$$\delta_{ij} = \frac{\sqrt{|C_i||C_j|}}{|G|} \sum_{k=1}^m \chi_{V_k}(g_i) \chi_{V_k}(g_j),$$

and so,

$$|C_i| = |G| \left(\sum_{k=1}^m |\chi_{V_k}(g_i)|^2 \right)^{-1}.$$

In the case that $C_i = \{e\}$ the trivial conjugacy class, we see that this formula provides $|G| = \sum |\chi_{V_k}(e)|^2 = \sum |\dim V_k|^2$.

Proposition 4.10. $\sum \dim V_i \chi_{V_i} = |G| \delta_e$.

Proof. Exercise. □

4.4 Normal Subgroups, Centre and Automorphisms

Recall that the kernel of a group homomorphism is a normal subgroup. In particular, as group representations are homomorphisms, a representation automatically provides a normal subgroup. We ask the converse where if we have a normal subgroup, can we construct a group representation.

Proposition 4.11. Let $N \trianglelefteq G$ be a normal subgroup of G . Let $V = \mathbb{C}[G/N]$ be the representation attached to the action

$$\rho_V : G \times G/N \rightarrow G/N : g \cdot hN \mapsto (gh)N.$$

Then $\ker \rho_V = N$.

Proof. $g \in \ker \rho_V \iff ghN = hN, \forall h \in G \iff h^{-1}gh \in N, \forall h \in G \iff g \in N$. □

So all normal subgroups are kernels of representation.

Proposition 4.12. $\ker \rho_{V \oplus W} = \ker \rho_V \cap \ker \rho_W$.

Proof. $g \in \ker \rho_{V \oplus W} \iff \rho_{V \oplus W}(g) = \text{id}_V \oplus \text{id}_W \iff \rho_V(g) = \text{id}_V \wedge \rho_W(g) = \text{id}_W \iff g \in \ker \rho_V \cap \ker \rho_W$. □

Corollary 5.5. For $|G| < \infty$, every normal subgroup is an intersection of kernels of irreducible representations.

Proof. Let $N \trianglelefteq G$, then $N = \ker \rho_{\mathbb{C}[G/N]}$. Then, by Maschke's, we may decompose $\rho_{\mathbb{C}[G/N]}$ into irreducible subrepresentations and so, N is the intersection of the kernels of these irreducible subrepresentations. □

Now, recall that if $|\chi_V(g)| = \dim V$, then $\rho_V(g) = \lambda \text{id}_V$ we have $\chi_V(g) = \dim V$ if and only if $\rho_V(g) = \text{id}$. Thus, $\ker \rho_V = \{g \in G \mid \chi_V(g) = \dim V\}$. With this we may classify the normal subgroups of a finite group by constructing the character table and see when $\chi_V(g) = \dim V$.

Consider $z \in Z(G)$ (where we denote $Z(G)$ for the centre of G , then $\rho_V(z) : V \rightarrow V$ is a G -linear map since for all $g \in G$, $\rho_V(z) \circ \rho_V(g) = \rho_V(zg) = \rho_V(gz) = \rho_V(g) \circ \rho_V(z)$. Thus, if V is irreducible, by Schur's lemma, $\rho_V(z) = \lambda \text{id}_V$ for some $\lambda \in \mathbb{C}$. Furthermore, we have $|\chi_V(z)| = \dim V$. The converse turns out to be also true.

Proposition 4.13. If G is finite and $|\chi_V(z)| = \dim V$ for all irreducible representations (V, ρ_V) , then $z \in Z(G)$.

Proof. If $|\chi_V(z)| = \dim V$, then $\rho_V(z) = \lambda \text{id}_V$. Then, for all $g \in G$, $\rho_V(z)\rho_V(g) = \lambda\rho_V(g) = \rho_V(g)\rho_V(z)$. Thus, by Maschke's, $\rho_V(zg) = \rho_V(z)\rho_V(g) = \rho_V(g)\rho_V(z) = \rho_V(gz)$ for all finite dimensional representations of G . Then, it suffices to find a faithful finite dimensional representation. In particular, the regular representation are faithful, and so $zg = gz$ for all $g \in G$ and hence, $z \in Z(G)$. \square

Proposition 4.14. The commutator subgroup is the intersection of the kernels of the 1-dimensional representations, i.e.

$$[G, G] = \bigcap_{\dim V=1} \ker \rho_V.$$

Proof. Recall that the 1-dimensional representations of G correspond to the 1-dimensional representations of G_{ab} , so $[G, G] \leq \ker \rho_V$ for $\dim V = 1$. Conversely, by considering that the intersection of all $\ker \rho_V$ for (V, ρ_V) 1-dimensional representations of G_{ab} must be the intersection of all normal subgroups of G_{ab} , this intersection must be $\{e\}$. \square

Recall that if we have a group homomorphism $\phi : G \rightarrow H$, then a representation (V, ρ_V) of H can be pulled back along ϕ to a representation of G with $(V, \rho_V \circ \phi)$. One can show that if ϕ is surjective, then (V, ρ_V) is irreducible if and only if $(V, \rho_V \circ \phi)$ is irreducible. So for ϕ surjective, this embeds a character table of H inside that of G .

Now, if $\phi : G \simeq H$ is an isomorphism, the character tables of G and H are identical up to reordering of rows and columns. In particular, an automorphism provides a symmetry for the character table in which $\chi(g) = (\chi \circ \phi^{-1})(\phi(g))$.

5 Algebras and Modules

So far we have looked at representations of groups and in most cases, finite groups. We will now turn our attention to something more general but before doing this, we will motivate this generalization with infinite groups.

Previously, we have seen that the characters of irreducible representations form an orthonormal basis of the class functions for finite groups. In the case of infinite groups this is no longer the case as we no longer have an inner product (provided we are not dealing with Haar measures). Nonetheless, we may still say something about their characters.

Proposition 5.1. If $(V_1, \rho_{V_1}), \dots, (V_m, \rho_{V_m})$ are finite dimensional non-isomorphic irreducible representations of G , then their characters $\chi_{V_1}, \dots, \chi_{V_m}$ are linearly independent.

Proof. Follows from proposition 5.2. \square

Also, we no longer require \mathbb{C} or an algebraically closed field since we will not be using Maschke's theorem. Nonetheless, we still require finite dimensional as otherwise we cannot even define the trace.

Lemma 5.1. Let (V, ρ) be a finite dimensional representation of G . Then, if $\rho(G)$ spans $\text{End}(V)$, then (V, ρ) is irreducible.

Proof. Suppose $W \subseteq V$ is a non-trivial subrepresentation and let $w \in W \setminus \{0\}$. Then, for all $v \in V$, take $T \in \text{End}(V)$, such that $T(w) = v$. As $\rho(G)$ spans $\text{End}(V)$, there exists a representation of T so that,

$$T = a_1 \rho(g_1) + \dots + a_m \rho(g_m).$$

Thus, $v = Tw = a_1 \rho(g_1)(w) + \dots + a_m \rho(g_m)(w)$. But now, as W is a subrepresentation of V , $\rho(g_i)(w) \in W$ for all i , and hence, by linearity, $v = a_1 \rho(g_1)(w) + \dots + a_m \rho(g_m)(w) \in W$ implying $W = V$. \square

The converse of this lemma is also true.

Proposition 5.2. Let (V, ρ) be an irreducible finite dimensional representation, then $\rho(G)$ spans $\text{End}(V)$. Furthermore, if $(V_1, \rho_{V_1}), \dots, (V_m, \rho_{V_m})$ are finite dimensional non-isomorphic irreducible representations, then $\{(\rho_1(g), \dots, \rho_m(g)) \mid g \in G\}$ spans $\text{End}(V_1) \oplus \dots \oplus \text{End}(V_m)$.

To understand and to prove these statements will require a more general theory, hence our study of algebras and modules.

5.1 Definitions

Definition 5.1 (\mathbb{C} -algebra). The group algebra of a group G is the free vector space $\mathbb{C}[G]$ equipped with the multiplication

$$\left(\sum a_g g\right) \left(\sum b_h h\right) = \sum_{g,h} a_g b_h gh,$$

where all but finitely many terms are zero.

We observe that a representation can extend linearly to the group algebra. In particular, if (V, ρ) is a representation of G , then we may define

$$\tilde{\rho}\left(\sum a_g g\right) := \sum a_g \rho(g) \in \text{End}(V).$$

Recall that $\text{End}(V)$ is a noncommutative ring with the multiplication $\phi\psi := \phi \circ \psi$ and we see that $\tilde{\rho}$ is a \mathbb{C} -linear ring homomorphism. Furthermore, we have $\tilde{\rho}|_G = \rho$. Thus, we have a bijection between the set of representations of G on V and the set of \mathbb{C} -linear ring homomorphisms from $\mathbb{C}[G]$ to $\text{End}(V)$.

Definition 5.2 (Algebra). An algebra A on a field F is a (not necessary commutative) ring which is also an F -vector space satisfying

$$c \cdot (ab) = (c \cdot a)b = a(c \cdot b),$$

for all $c \in F$, $a, b \in A$.

Equivalently, one may define an algebra to be a ring A equipped with a injective ring homomorphism $F \hookrightarrow Z(A)$ where F is a field and $Z(A) := \{z \in A \mid \forall a \in A, az = za\}$, i.e. the A contains F in its centre.

Definition 5.3 (Algebra Homomorphism). Given A, B F -algebras, a F -algebra homomorphism is a map $\phi : A \rightarrow B$ that is a ring homomorphism and F -linear.

If A is an \mathbb{F} -algebra, then there is always an algebra homomorphism $F \rightarrow A$ given by $\lambda \mapsto \lambda \cdot 1_A$.

Definition 5.4 (Module). A module over an F -algebra A is a pair (V, ρ) where V is a F -vector space and $\rho : A \rightarrow \text{End}(V)$ in an algebra homomorphism.

As demonstrated above, if (V, ρ) is a representation, then $(V, \tilde{\rho})$ is a module over $\mathbb{C}[G]$.

If V is a F -vector space, it is easy to see that $A := \text{End}(V)$ is an F -algebra, and furthermore, A is an module over itself by taking $\rho := \text{id}_A$.

Another famous example is known as the Gelfand-Naimark duality. If X is a compact Hausdorff topological space, then there is an theorem stating that we have an equivalence between X and its algebra of continuous functions $C(X)$. In particular, given a continuous function $\phi : X \rightarrow Y$, we have its pull-back $\phi^* : C(Y) \rightarrow C(X) : f \mapsto f \circ \phi$ in the commutative C^* -algebras (see the functional analysis course).

Similarly, in algebraic geometry, we study the duality between the varieties, i.e.

$$X = \{f_1(x_1, \dots, x_n) = \dots = f_m(x_1, \dots, x_n) = 0 \mid f_1, \dots, f_m \in \mathbb{C}[x_1, \dots, x_n]\} \subseteq \mathbb{C}^n$$

and algebras $\mathcal{O}(X) := \mathbb{C}[x_1, \dots, x_n]/(f_1, \dots, f_m)$.

Definition 5.5 (Submodule). A submodule of a module (V, ρ_V) over A is a subspace $W \leq V$ such that, $\rho_V(a)(W) \subseteq W$ for all $a \in A$.

Definition 5.6 (Module Homomorphism). A module homomorphism between to modules (V, ρ_V) and (W, ρ_W) is a linear map $T : V \rightarrow W$ such that $T \circ \rho_V(a) = \rho_W(a) \circ T$ for all $a \in A$. We denote $\text{Hom}_A(V, W)$ for the set of module homomorphisms between (V, ρ_V) and (W, ρ_W) .

Definition 5.7 (Decomposable). A module (V, ρ_V) is decomposable if there exists proper submodules W_1, W_2 such that $V = W_1 \oplus W_2$. We say a module is indecomposable if it is not decomposable unless $V = 0$.

Definition 5.8 (Reducible). A module (V, ρ_V) is reducible if there exists a non-trivial, proper submodule W . If (V, ρ_V) is not reducible, then we say it is simple (or irreducible) unless $V = 0$.

Definition 5.9 (Semisimple). A module (V, ρ_V) is semisimple if there exists simple submodules W_1, \dots, W_m such that $V = W_1 \oplus \dots \oplus W_m$.

We see that these definition are essentially the same as the ones for representations. Indeed, as justified earlier, a module is simply representations of algebras.

Definition 5.10 (Regular Module). Let A be an algebra, then the regular module over A is A over itself equipped with the algebra homomorphism

$$\rho : A \mapsto \text{End}(A) : a \mapsto a(\cdot).$$

We will continue to work with \mathbb{C} though all following statements also work for any algebraically closed field.

Lemma 5.2 (Schur's Lemma). If $T : V \rightarrow W$ is a module homomorphism and V is simple, then T is either 0 or an faithful (in the case that W is also simple, then T is an isomorphism). Furthermore, if V is simple and finite dimensional, then $\text{End}_A(V) = \mathbb{C} \cdot \text{id}_V$.

Proof. Same proof as the representation case. □

Proposition 5.3. If (V, ρ_V) is an A -module and $\rho_V : A \rightarrow \text{End}(V)$ is surjective, then (V, ρ_V) is simple. Furthermore, if V is finite dimensional, then the converse holds.

While similar to the representation case, we may define the external direct sum of two modules, unlike the representation case, we may not define the tensor product as the scalar multiplication operation is linear, not bilinear. Indeed, if we have something called a bi-algebra, then it is possible to define the tensor product.

5.2 Semisimplicity and Matrix Algebras

We recall that finite dimensional representations of G over \mathbb{C} are semi simple. Thus, by the bijective correspondence, the same is true for finite dimensional modules over the group algebra $\mathbb{C}[G]$. Also recall that we have the isomorphism $\mathbb{C}[G] \rightarrow \bigoplus \text{End}(V_i)$ if $(V_1, \rho_{V_1}), \dots, (V_m, \rho_{V_m})$ are irreducible up to isomorphism, and in fact, we now see this is also a algebra homomorphism.

Definition 5.11 (Semisimple Algebra). For $\dim_F A < \infty$, A is said to be semisimple if every finite dimensional A -module is semisimple.

Lemma 5.3. If (V, ρ_V) is an A -module, and $v \in V \setminus \{0\}$, we define $\phi_v : A \rightarrow V : a \mapsto \rho_V(a)(v)$. Then ϕ_v is a surjective A -module homomorphism if V is simple.

Proof. $\phi_v(A) \subseteq V$ is a submodule and so, $\phi_v(A) = \{0\}$ or $\phi_v(A) = V$. This first case is impossible since $\phi_v(e) = \rho_V(e)(v) = v \neq 0$. □

With this in mind, we see that we can find all simple modules from A by considering $V \cong A/\ker \phi_v$ by the first isomorphism theorem.

Proposition 5.4. Every simple A -module is isomorphic to V .

Proof. If (W, ρ_W) is simple and $w \in W \setminus \{0\}$, then we have $W \cong A/\ker \phi_w$. It is clear that $\ker \phi_w \neq \{0\}$ and $\ker \phi_w \neq A$ and so, $\ker \phi_w = V$. Applying $W = V$, we obtain $V \cong A/V$ and so $W \cong A/V \cong V$. \square

Proposition 5.5. If $V = V_1 \oplus \cdots \oplus V_m$ where V_i is simple for all i , then every submodule $U \subseteq V$ has a complementary submodule of the form

$$V_I = \bigoplus_{i \in I} V_i, \text{ for some } I \subseteq \{1, \dots, m\}.$$

Proof. Let $I \subseteq \{1, \dots, m\}$ be maximal such that $U \cap V_I = \{0\}$. Then $V = U \cup V_I$ since if otherwise, for some $i \in I$, $V_i \not\subseteq U \oplus V_I$. But, as V_i is simple, we have $V_i \cap U \oplus V_I = \{0\}$ and so $U \cap (V_i \oplus V_I)$ contradicting the maximality of I . \square

Corollary 5.6. Every submodule and quotient module of a semisimple module is semisimple.

Proof. Let $U \subseteq V = \bigcup_i V_i$ be a submodule and suppose it has complement V_I . Then $V/U \cong U \oplus V_i/U \cong V_I$ which is semisimple.

Similarly, the composition of the inclusion map $\iota : U \rightarrow V$ and the quotient map $q : V \rightarrow V/V_I$ is an isomorphism implying U is semisimple. \square

Lemma 5.4. Let V be an n -dimensional module over A , then V is isomorphic to a quotient module of A^n .

Proof. Let $\{v_1, \dots, v_n\}$ be a basis of V and define the surjection

$$\phi : (a_1, \dots, a_n) \mapsto a_1 v_1 + \cdots a_n v_n = \rho(a_1)(v_1) + \cdots + \rho(a_n)(v_n).$$

Then $V \cong A^n / \ker \phi$ as required. \square

Proposition 5.6. A is semisimple if and only if A is semisimple as a (left regular) module over itself.

Proof. The forward direction is clear so let us consider the reverse.

Suppose A is a semisimple A -module and let V be a finite-dimensional A -module. Then, by the above lemma, V is isomorphic to some quotient module of A^n and so, it suffices to show A^n is semisimple. But this is clear since $A^n = A \oplus \cdots \oplus A$ and the direct sum of semisimple modules is semisimple. \square

Definition 5.12 (Opposite Algebra). Given an algebra A , the opposite algebra A^{op} is the algebra A with the reversed multiplication, i.e. $a \cdot_{op} b = ba$.

We note that the same construction can be made for groups but $G \simeq G^{op}$ by the map $g \mapsto g^{-1}$.

Lemma 5.5. The map $\text{End}_A A \rightarrow A^{op} : \phi \mapsto \phi(1_A)$ is an algebra isomorphism.

Proof. The inverse is $a \mapsto \phi_a$ where $\phi_a(b) := ba$. \square

Theorem 6 (Artin-Wedderburn). Given a finite dimensional algebra A , the following are equivalent:

1. every finite dimensional A -module is semisimple, i.e. A is semisimple;
2. A is isomorphic to a direct sum of matrix algebras, i.e. $A \cong \bigoplus_{i=1}^m \text{Mat}_{n_i}(\mathbb{C})$;
3. there is a full set of simple left A -modules V_1, \dots, V_m and an isomorphism $A \cong \bigoplus_{i=1}^m \text{End}(V_i)$.

We see that both the second and third statement implies the sum of squares formula.

Proof. It is clear that 2 and 3 are equivalent by simply picking basis.

We will now show 2 implies 1. Recall that A is semisimple if and only if A is semisimple as a (left regular) A -module over itself and since $A \cong \bigoplus \text{Mat}_{n_i}(\mathbb{C})$, it suffices to show $\bigoplus \text{Mat}_{n_i}(\mathbb{C})$ is semisimple over itself. Recalling that \mathbb{C}^{n_i} is semisimple as a $\text{End}(\mathbb{C}^{n_i})$ -module and $\text{Mat}_{n_i}(\mathbb{C}) \cong \mathbb{C}^{n_i} \oplus \dots \oplus \mathbb{C}^{n_i}$, we have $\text{Mat}_{n_i}(\mathbb{C})$ is a semisimple $\bigoplus_i \text{Mat}_{n_i}(\mathbb{C})$ implying the result.

Finally, we will show 1 implies 2. Suppose A is semisimple and let write $A = V_1^{r_1} \oplus \dots \oplus V_n^{r_n}$ where V_i are pair-wise nonisomorphic. As we have shown above, $\text{End}_A A \cong A^{op}$ and so,

$$A^{op} \cong \text{End}_A(V_1^{r_1} \oplus \dots \oplus V_n^{r_n}) \cong \text{Mat}_{r_1}(\mathbb{C}) \oplus \dots \oplus \text{Mat}_{r_n}(\mathbb{C}).$$

On the other hand, $\text{Hom}(V_i^{r_i}) \cong \text{Mat}_{r_i}(\mathbb{C})$ by Schur's lemma, and thus we have 1 implies 2. \square

5.3 Character Theory and Abstract Traces

We again visit character theory in the point of view of modules and we will show that, in general algebras, the map $A \rightarrow \text{End}(V)$ is surjective (Artin-Wedderburn tells us that if A is finite dimensional and semisimple then the map is an isomorphism).

Proposition 5.7. Let A be an algebra and V_1, \dots, V_m be non-isomorphic simple finite-dimensional A -modules, then the map

$$\bigoplus_{i=1}^m \rho_{V_i} : A \rightarrow \bigoplus_{i=1}^m \text{End}(V_i)$$

is surjective.

Proof. Let $B = \bigoplus_i \rho_{V_i}(A) \subseteq \bigoplus_i \text{End}(V_i)$, then B is an A -module under left multiplication, i.e.

$$\rho_V(a)(b) = (\rho_{V_1}(a), \dots, \rho_{V_m}(a))b.$$

Then, since V_i is semisimple, $\text{End}(V_i) \cong V_i^{\dim V_i}$ and so, B is semisimple. Thus, as B is finite dimensional, it is a semisimple algebra. Now, by observing that V_i are simple, non-isomorphic B -modules, by Artin-Wedderburn, for $V_1, \dots, V_m, W_1, \dots, W_n$ all simple B -modules, we have

$$B \cong \bigoplus \text{End}(V_i) \oplus \bigoplus \text{End}(W_i).$$

But $B \subseteq \bigoplus \text{End}(V_i)$, and so, by dimensional argument, we have $B = \bigoplus \text{End}(V_i)$ and hence, the map is surjective. \square

Definition 5.13 (Character). Given a finite dimensional A -module (V, ρ_V) , we define its character to be

$$\chi_{\rho_V}(a) := \text{tr}(\rho_V(a)).$$

Proposition 5.8. Given $\{V_i\}$ non-isomorphic simple finite-dimensional A -modules, $\{\chi_{V_i}\}$ are linearly independent.

Proof. Suppose $\lambda_1 \chi_{V_1} + \dots + \lambda_m \chi_{V_m} = 0$. Then, by the above proposition, $A \rightarrow \bigoplus \text{End}(V_i)$ is surjective and so, for all j , there exists some $a \in A$ such that $\text{tr}(\rho_{V_j}(a)) = 1$ and $\rho_{V_i}(a) = 0$ for all $i \neq j$. Then,

$$0 = \lambda_1 \chi_{V_1}(a) + \dots + \lambda_m \chi_{V_m}(a) = \lambda_j$$

for each j . Hence $\{\chi_{V_i}\}$ are linearly independent. \square

Corollary 6.1. Let G be a (not necessary finite) group and V_1, \dots, V_m be non-isomorphic, finite dimensional, irreducible representations of G . Then, $\chi_{V_1}, \dots, \chi_{V_m}$ are linearly independent.

Recall that given an irreducible, finite dimensional representation (V, ρ_V) , the character χ_V is a class function by the property of the trace. We would like to generalize this notion for algebras. In particular, we note that the character satisfy

$$\chi_{\rho_V}(ab) = \text{tr} \rho_V(ab) = \text{tr}(\rho_V(a) \rho_V(b)) = \text{tr}(\rho_V(b) \rho_V(a)) = \chi_{\rho_V}(ba).$$

Definition 5.14. An abstract (or Hochschild) trace is a functional

$$\phi : A \rightarrow \mathbb{C}$$

such that $\phi(ab) = \phi(ba)$ for all $a, b \in A$.

Equivalently, we $\phi(ab - ba) = 0$ for all $a, b \in A$ which implies $[A, A] \leq \ker \phi$ where $[A, A] = \text{span}\{ab - ba \mid a, b \in A\}$. $[A, A]$ is known as the additive commutator and is analogues to the group commutator. Thus, by the universal property of the quotient, an abstract trace is uniquely identified by the map $\phi : A/[A, A] \rightarrow \mathbb{C}$ where $A/[A, A] \cong HH_0(A)$ where $HH_0(A)$ is known as the zeroth Hochschild homology.

We note that in the group case, where we defined the class function to be functions $\phi : G \rightarrow \mathbb{C}$ which satisfy $\phi(hgh^{-1}) = \phi(g)$, an abstract trace is the same as a class function.

Definition 5.15. With the above remark in mind, we have

$$\{\text{abstract traces}\} \cong \left(\frac{A}{[A, A]} \right)^*$$

where $*$ denotes the dual, and so, we define $A_{\text{tr}}^* \subseteq A^*$ the space of abstract traces.

It is clear that characters are abstract traces.

Recall that in the group case, by Mascke's theorem, if $W \leq V$ is a subrepresentation, then we have $\chi_V = \chi_W + \chi_{W^\perp}$ where W^\perp is the complement of W . We cannot do this in general for algebras though we may do something similar.

Given a submodule $W \leq V$, we can always take its quotient V/W .

Proposition 5.9. For $W \leq V$ a submodule where V is a finite dimensional module, we have

$$\chi_V = \chi_W + \chi_{V/W}.$$

Proof. Let B be a basis of W and extend $B \cup C$ to a basis of V . Then

$$[\rho_V(a)]_{B \cup C} = \begin{pmatrix} [\rho_W(a)]_B & \star \\ 0 & [\rho_{V/W}(a)]_{C+V} \end{pmatrix}.$$

Thus, $\chi_V = \chi_W + \chi_{V/W}$ as required. \square

We note that in this case where the module is non-semisimple (i.e. it contains a submodule without being decomposable) the character no longer uniquely characterizes the module. Indeed, for V non-semisimple and $W \leq V$ a submodule,

$$\chi_V = \chi_W + \chi_{V/W} = \chi_{W \oplus V/W},$$

yet $V \not\cong W \oplus V/W$.

Corollary 6.2. If (V, ρ_V) is *any* finite dimensional module of A , then χ_V is a sum of irreducible characters (characters of simple module).

Corollary 6.3. The irreducible character form a basis for the span of all characters of finite dimensional modules. In particular, the span of all characters is a subspace of A_{tr}^* though it might not be the whole space.

If A is commutative, then $[A, A] = 0$ and so, $A \cong A^* = A_{\text{tr}}^*$. In this case, the irreducible characters form a basis for A_{tr}^* if and only if $\dim A$ equals to number of 1-dimensional modules (modulo isomorphisms) (since 1-dimensional modules are simple and hence, their characters are linearly independent). In this case, the surjection

$$A \rightarrow \bigoplus_{V_i \text{ simple}} \text{End}(V_i)$$

is a isomorphism. Now, since for 1-dimensional module V_i , $\text{End}(V_i) \cong \mathbb{C}$, we have $A \cong \mathbb{C}^{\dim A}$.

Proposition 5.10. For A a finite dimensional, semisimple algebra, the irreducible characters form a basis for A_{tr}^* . More generally, we have

- $\dim A_{\text{tr}}^* \geq \# \text{ simple modules};$
- $\dim A \geq \sum_{V_i \text{ simple}} (\dim V_i)^2.$

Finally, a finite dimensional A is semisimple if and only if $\dim A = \sum_{V_i \text{ simple}} (\dim V_i)^2$.

Proof. We already know $\dim A_{\text{tr}}^* \geq \# \text{ simple modules}$ and the surjection $A \rightarrow \bigoplus \text{End}(V_i)$ implies $\dim A \geq \sum_{V_i \text{ simple}} (\dim V_i)^2$. Furthermore, we have $\dim A = \sum_{V_i \text{ simple}} (\dim V_i)^2$, then the map $A \rightarrow \bigoplus \text{End}(V_i)$ is an isomorphism which occurs if and only if A is semisimple by Artin-Wedderburn.

Now, suppose A is finite dimensional and semisimple, I claim that

$$[\text{End}(V_i), \text{End}(V_i)] = \{T \in \text{End}(V_i) \mid \text{tr}(T) = 0\},$$

for all simple V_i . This follows by choosing a basis and considering the elementary matrices $E_{ij} = (\delta_{ij})_{ij}$ where we have $[E_{ij}, E_{kl}] = \delta_{jk}E_{il} - \delta_{il}E_{kj}$. Hence, any diagonal entries is eliminated implying the trace is zero. Thus, $\text{End}(V_i)^*_{\text{tr}} = \mathbb{C} \cdot \text{tr}$ implying

$$A_{\text{tr}}^* \cong \left(\bigoplus \text{End}(V_i) \right)_{\text{tr}}^* = \bigoplus \mathbb{C} \cdot \text{tr}_{V_i},$$

where $\text{tr}_{V_i} = \chi_{V_i}$ implying the character forms a basis of A_{tr}^* . \square

5.4 Centre and Projections

Definition 5.16 (Centre of an Algebra). Given an algebra A , we define its centre to be

$$Z(A) := \{z \in A \mid za = az, \forall a \in A\}.$$

Alternatively, we may define the map $\text{ad} : A \rightarrow \text{End}_{\mathbb{C}}(A) : a \mapsto \text{ad}(a)$ where $\text{ad}(a) : b \mapsto [a, b]$ and then, $Z(A) = \ker \text{ad}$.

We observe that if $z \in Z(A)$ and V is a finite dimensional, simple module, then Schur's lemma implies $\rho_V(z) = \lambda \cdot \text{id}_V$ for some $\lambda \in \mathbb{C}$ (as $\rho_V(z)$ is A -linear).

Proposition 5.11. $Z(\text{End}(V)) = \mathbb{C} \cdot \text{id}_V$.

Proof. This follows by taking a basis and observing that the matrices which commutes with all other matrices are multiples of the identity matrix.

Alternatively, we may prove this using representation theory. Recall that V is a simple module over $\text{End}(V)$ with $\rho_V = \text{id}_{\text{End}(V)}$. Then, for all $z \in Z(V)$, by Schur's lemma, $\rho_V(z) = \lambda \cdot \text{id}_V$ for some $\lambda \in \mathbb{C}$. But $\rho_V(z) = z$ as ρ_V is the identity, and thus, $z = \lambda \cdot \text{id}_V$ and hence, $Z(\text{End}(V)) = \mathbb{C} \cdot \text{id}_V$. \square

Proposition 5.12. If $\phi : A \rightarrow B$ is an isomorphism of algebras, then the restriction of ϕ onto its centre $\phi|_{Z(A)} : Z(A) \rightarrow Z(B)$ is also an isomorphism.

Corollary 6.4. The isomorphism $\Phi : \mathbb{C}[G] \cong \bigoplus_{i=1}^m \text{End}(V_i)$ restricts to an isomorphism

$$\Phi|_{Z(\mathbb{C}[G])} : Z(\mathbb{C}[G]) \cong \bigoplus_{i=1}^m \mathbb{C} \cdot \text{id}_{V_i}.$$

Proposition 5.13. Let G be a group and let $\mathcal{C}_1, \dots, \mathcal{C}_m$ be the conjugacy classes of G , then denoting

$$c_i := \sum_{g \in \mathcal{C}_i} g \in \mathbb{C}[G],$$

c_1, \dots, c_m form a basis of $Z(\mathbb{C}[G])$ and thus, $\dim Z(\mathbb{C}[G]) = m$.

Proof. Linear independence follows since $\mathcal{C}_i \cap \mathcal{C}_j = \emptyset$, and so it suffice to show spanning. Consider for all $x = \sum_{g \in G} x_g g \in \mathbb{C}[G]$, I claim that $x \in Z(\mathbb{C}[G])$ if and only if $x_g = x_{hgh^{-1}}$ for all $h \in G$. Indeed, if $x \in Z(\mathbb{C}[G])$, then

$$x = h^{-1}xh = \sum_{g \in G} x_g h^{-1}gh = \sum_{hgh^{-1} \in G} x_{hgh^{-1}}g = \sum_{g \in G} x_{hgh^{-1}}g.$$

Thus, $x_g = x_{hgh^{-1}}$ for all $h \in G$. On the other hand, if $x_g = x_{hgh^{-1}}$ for all $h \in G$, then for all $y = \sum_{g \in G} y_g g \in \mathbb{C}[G]$, we have

$$\begin{aligned} xy &= \sum_{g, h \in G} (x_g y_h) \cdot gh = \sum_{hgh^{-1}, h \in G} (x_{hgh^{-1}} y_h) \cdot (hgh^{-1})h \\ &= \sum_{hgh^{-1}, h \in G} (x_g y_h) \cdot gh = \sum_{g, h \in G} (x_g y_h) \cdot gh = yx \end{aligned}$$

implying $x \in Z(\mathbb{C}[G])$ as required. Hence, it follows c_1, \dots, c_m spans $Z(\mathbb{C}[G])$. \square

Corollary 6.5. Since $Z(\mathbb{C}[G]) \cong \bigoplus_{i=1}^m \mathbb{C} \cdot \text{id}_{V_i}$, taking the dimension on both sides, we again obtain that the number of conjugacy classes equals the number of irreducible representations.

In summary, we have the following three equivalent statements:

- $a \in \mathbb{C}[G]$ is central,
- $a = \sum a_g g \in \mathbb{C}[G]$ where $a_g = a_{hgh^{-1}}$ for all $g, h \in G$,
- for all irreducible representations (V, ρ_V) , $\rho_V(a) = \lambda_a \cdot \text{id}_V$ for some $\lambda_a \in \mathbb{C}$.

Proposition 5.14. If A is a finite dimensional, semisimple algebra, then we have the isomorphism

$$A_{\text{tr}}^* \rightarrow Z(A)^* : \phi \mapsto \phi|_{Z(A)}.$$

Proof. By Artin-Wedderburn, it suffices to show the statement for $A = \text{Mat}_n(\mathbb{C})$. Recall that $(\text{Mat}_n(\mathbb{C}))_{\text{tr}}^* = \mathbb{C} \cdot \text{tr}$ and $Z(\text{Mat}_n(\mathbb{C}))^* = (\mathbb{C} \cdot I_n)^*$ and so, the map becomes

$$\lambda \cdot \text{tr} \mapsto (\mu I \mapsto n\lambda\mu),$$

since $\text{tr}(\mu I) = n\mu$. This is clearly an isomorphism of 1-dimensional vector spaces and so we have the required isomorphism. \square

Now that we have established the isomorphism $Z(\mathbb{C}[G]) \cong \bigoplus_{i=1}^m \mathbb{C} \cdot \text{id}_{V_i}$, we would like to ask the preimage of id_{V_i} along this isomorphism. By definition, let us write $\rho_{V_i}(z) = \lambda_{z,i} \cdot \text{id}_{V_i}$ for all $z \in Z(\mathbb{C}[G])$. Then, we have $\chi_{V_i}(z) = \lambda_{z,i} \dim V_i$, and so,

$$\lambda_{z,i} = \frac{1}{\dim V_i} \chi_{V_i}(z).$$

Hence, if z is such that $\chi_{V_i}(z) = \dim V_i$ and $\chi_{V_j}(z) = 0$ for all $j \neq i$, then we obtain that z is mapped to id_{V_i} along this isomorphism.

Let us define

$$e_{V_i} := \frac{\dim V_i}{|G|} \sum_{g \in G} \overline{\chi_{V_i}(g)} g.$$

Then, we have

$$\chi_{V_j}(e_{V_i}) = \frac{\dim V_i}{|G|} \sum_{g \in G} \overline{\chi_{V_i}(g)} \chi_{V_j}(g) = \dim V_i \delta_{ij}.$$

Hence, $\rho_{V_j}(e_{V_i}) = \delta_{ij} \cdot \text{id}_{V_i}$ is a G -linear projection with the image being V_i . In particular, we have the isomorphism

$$(\rho_{V_1}(e_{V_1}), \dots, \rho_{V_n}(e_{V_n})) : V \cong V^1 \oplus \dots \oplus V^n.$$

We say the this map decomposes V into isotypic components, i.e. V^i is the span of all subrepresentations of V isomorphic to V_i .

6 Connections to Geometry

This section will provide some connections between representation theory to geometry. All content in this section are not examinable.

6.1 Dirac Operator and Clifford Algebra

The Dirac operator is an operator initially motivated by relativistic quantum mechanics and is defined to be a square root of the Laplacian operator, i.e. the Dirac operator D is an operator such that

$$D^2 = \Delta = \frac{\partial^2}{\partial x_1^2} + \cdots + \frac{\partial^2}{\partial x_n^2}.$$

The non-relativistic Schrödinger equation (without potential, i.e. free particle) is

$$i\hbar \frac{\partial \psi}{\partial t} = -\frac{\hbar^2}{2m} \Delta \psi$$

where $\psi : \mathbb{R}^n \rightarrow \mathbb{C}$ is the wave function evolving in time. Written in terms of the Hamiltonian H , we have the equation $\dot{\psi} = H\psi$ (omitting some constants). We note that this equation treats time and space separately and is therefore non-relativistic.

In relativity on the other hand, we have the momentum-energy four-vector

$$p^2 c^2 + m^2 c^4 = E^2$$

where p is the momentum, c is the speed of light, m is the mass and E is the energy. This equation suggests another operator describing energy (in contrast to the Hamiltonian) and so, we replace the Schrödinger equation with

$$\frac{1}{c^2} \left(i\hbar \frac{\partial}{\partial t} \right)^2 \psi + \hbar^2 \Delta \psi = m^2 c^2 \psi.$$

Denoting the operator $\tilde{\Delta} := \left(\frac{i\hbar}{c} \frac{\partial}{\partial t} \right)^2 + \left(\hbar \frac{\partial}{\partial x_1} \right)^2 + \cdots + \left(\hbar \frac{\partial}{\partial x_n} \right)^2$, the equation becomes $\tilde{\Delta} \psi = m^2 c^2 \psi$. We call $\tilde{\Delta}$ the space-time Laplacian. However, unlike the Schrödinger equation, this is now a second order differential equation and the solution will depend on not only the wave function at time 0, but also its derivative at 0. This is problematic as the derivative might be badly behaved and ψ might not be L^2 .

Now, if there exists an operator D such that $D^2 = \tilde{\Delta}$, we can solve $D\psi = mc\psi$ and this equation is known as the Dirac equation. Although it is not yet clear such an operator exists.

For simplicity, assume we are working with the usual Laplacian Δ though it is not difficult to generalize these ideas.

In the case $n = 1$, D is simply the derivative and indeed, $D^2 = \frac{d^2}{dx^2} = \Delta$. For higher dimensions, we will need to use matrices with the solutions being vectors. In particular, for $n = 2$, we may take

$$\left(\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \frac{\partial}{\partial x} + \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \frac{\partial}{\partial y} \right)^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} = \Delta,$$

which acts on a vector of functions $(f_1, f_2)^T$. Similarly, for $n = 3$, we have

$$\left(\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \frac{\partial}{\partial x} + \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \frac{\partial}{\partial y} + \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \frac{\partial}{\partial z} \right)^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} = \Delta.$$

These matrices are known as Pauli matrices and anticommute. In relativity, we are interested in $n = 4$ (3 space dimensions and 1 time dimension) and in this case, we will need 4×4 matrices acting on $(f_1, \dots, f_4)^T$.

From an abstract point of view, we want in general

$$D = \sum_{i=1}^n e_i \frac{\partial}{\partial x_i} \text{ where } e_i e_j = -e_j e_i, e_i^2 = 1$$

for all $i, j = 1, \dots, n, i \neq j$.

Definition 6.1 (Clifford Algebra). The Clifford algebra is

$$\mathbb{C}l_n := \frac{\mathbb{C}\langle e_1, \dots, e_n \rangle}{\langle e_i e_j = -e_j e_i, e_1^2 = \dots = e_n^2 = 1 \rangle}.$$

We use the angled brackets to stress e_i do not commute.

Theorem 7 (Algebraic version of Bott periodicity). $\mathbb{C}l_{2n} \cong \text{Mat}_{2^n}(\mathbb{C})$ and $\mathbb{C}l_{2n+1} \cong \text{Mat}_{2^n}(\mathbb{C}) \oplus \text{Mat}_{2^n}(\mathbb{C})$.

Corollary 7.1. $\mathbb{C}l_n$ is semisimple and for even n , we have the unique 2^n -dimensional module and for odd n , we have the two unique 2^n -dimensional modules.

As a consequence, a Dirac operator D satisfying $D^2 = \Delta$ on \mathbb{R}^n , we require matrices of size $2^{\lfloor n/2 \rfloor}$. Thus, solutions of $D\psi = \lambda\psi$ are vectors of functions $(f_1, \dots, f_N)^T$ where $N = 2^{\lfloor n/2 \rfloor}$.

Definition 6.2 (Real Clifford Algebra). The real Clifford algebra is

$$Cl_{\mathbb{R}}(p, q) := \frac{\mathbb{R}\langle x_1, \dots, x_{p+q} \rangle}{\langle x_i x_j + x_j x_i = 0, x_1^2 = \dots = x_p^2 = 1, x_{p+1}^2 = \dots = x_{p+q}^2 = -1 \rangle}.$$

We note $Cl_{\mathbb{R}}(0, q)$ is \mathbb{R} for $q = 0$, \mathbb{C} for $q = 1$ and \mathbb{H} for $q = 2$.

With this in mind, the Pauli matrices are simply the values of the Clifford algebra written as matrices.

6.1.1 The Spin Group

Let us recall the orthogonal and special orthogonal group. In particular, we have the groups

$$O(n, \mathbb{R}) := \{A \in GL_n(\mathbb{R}) \mid A^T = A^{-1}\},$$

and

$$SO(n, \mathbb{R}) := \{A \in O(n, \mathbb{R}) \mid \det A = 1\}.$$

In particular, as $A^T = A^{-1}$ implies $\det A = \pm 1$, we may think the orthogonal group as the group of isometries while the special orthogonal group as the subgroup of the orthogonal group which preserves the orientation.

We observe that $O(n, \mathbb{R})$ preserves the dot product and the norm, and so, it preserves the Laplacian. With this, the orthogonal group acts on the Clifford algebra where $e_i \mapsto Ae_i$ for all $A \in O(n, \mathbb{R})$. Furthermore, these actions can be obtained by conjugation. With this, conjugation provides a surjective homomorphism from S^3 to $SO(3, \mathbb{R}) \hookrightarrow \mathbb{R}i \oplus \mathbb{R}j \oplus \mathbb{R}k$ where the map has kernel $\{\pm 1\}$ (the center). With this, $SO(3, \mathbb{R})$ has a nontrivial covering S^3 and this is called the “spin group”.

We may construct the spin group in general using the Clifford algebra. Inside $Cl_{\mathbb{R}}(0, n)$, we have the unit vectors $v \in \mathbb{R}^n \subseteq Cl_{\mathbb{R}}(0, n)$, i.e. $v \cdot v = 1 \iff v^2 = -1$ in $Cl_{\mathbb{R}}(0, n)$. Now, the mapping $w \mapsto v w v$ is a reflection as $v^2 = -1$. Generally, defining

$$\text{Pin}(n, \mathbb{R}) := \langle v \in \mathbb{R}^n \mid v^2 = -1 \rangle \rightarrow O(n, \mathbb{R}) : v \mapsto (w \mapsto v w v),$$

we have a subgroup $\text{Spin}(n, \mathbb{R}) \leq \text{Pin}(n, \mathbb{R})$ such that

$$\text{Spin}(n, \mathbb{R}) := \langle v, w \in \mathbb{R}^n \mid v^2 = -1 = w^2 \rangle \rightarrow SO(n, \mathbb{R})$$

which maps product of even number of unit vectors to the product of even number of reflections. One may similarly define $\text{Spin}(n, \mathbb{C}) \subseteq \text{Cl}(n)$ and $\text{Spin}(p, q, \mathbb{R}) \subseteq Cl_{\mathbb{R}}(p, q)$.

Generally, spin and pin do act as subgroups of the Clifford algebra. As a consequence of this, using the compatibility of the spinor $2^{\lfloor n/2 \rfloor}$ -dimensional module over the Clifford algebra with orthogonal transformations, we can define the Dirac operator not just on \mathbb{R}^n but on “spin” manifolds.

Proposition 6.1. The irreducible representations of $SO(n, \mathbb{R})$ are natural subspaces of $(\mathbb{R}^n)^{\otimes m}$ for $m \geq 0$ up to isomorphism.

Proposition 6.2. The irreducible complex representations of $\text{Spin}(n, \mathbb{R})$ are the above and the natural subspaces of the $2^{\lfloor n/2 \rfloor}$ -dimensional representations of $\text{Cl}(n)$ and their tensor powers up to isomorphism.
